Having developed a relevant qualification, the next hurdle was to develop a means of delivering learning and assessment that would be accessible to a market that was poorly resourced, geographically spread, and vocationally disparate.

It was clear from an early stage that conventional methods of study – day release, evening classes, and even intensive block release – were inappropriate. It was inconceivable that students spread across the south west peninsula (some 150 mile long with slow rail links and dubious roads) would be able to congregate on a regular basis to pursue their studies. The demands of their jobs alone, notwithstanding domestic or financial constraints, meant that opportunities to meet together would be at a premium.

The obvious solution lay in some kind of distance learning approach, and initially we debated the possibility of a straightforward web based e learning programme. This would be accessed by individuals from home or from their places of work and would offer all the benefits of asynchronicity that their circumstances might demand.

However, while this appeared an ideal solution in many ways, it overlooked two key factors that had already been evident from pilot work with this particular student group. Firstly, managers in the voluntary sector do not necessarily have either sophisticated computer skills or even access to reliable computer equipment. Secondly, experience to date had shown that, perhaps because of their relative isolation, managers in the sector reported huge personal and professional benefits from being able to meet together to discuss common issues and share experiences. Indeed, where training had been provided by Exeter Council for Voluntary Services in the past, participants often reported as much benefit arising from the opportunity of making contact with their counterparts as they did from the immediately intended outcomes of the programme.

The decision was therefore taken that the needs of this particular group would be best met by means of a blended learning approach. This would enable us to offer a mix of delivery methods suited to these managers:

- A small number of intensive 'all course' sessions to cover induction, technical training, and key issues
- A greater number of smaller group localised 'tutorials' which would enable learners to meet together to share experiences, discuss progress, debate specific topics and to receive personalised feedback
- A variety of web based learning and assessment opportunities accessible at times to suit the learners' individual circumstances
- Ongoing access to e moderated tutorial support and bulletin board discussions
- Localised technical support to facilitate both the learning and the use of IT in the learners' own organisations

However, there were two significant barriers still to be overcome before such a system could be put in place.

Firstly, the financial demands of developing and implementing such a programme far exceeded the normal resource available to a state funded provider of higher education, particularly where it was unlikely that the learners themselves, or their employers, would be in a position to subsidise the process.

Secondly, there was little pre-existing experience or expertise within the participating educational organisations to support such a development. In many parts of the UK, the idea of VLEs and MLEs, while they might feature in a College or University's five year strategic plan, are still a long way from full implementation.

As a consequence, we put in a bid to the European Social Fund for support in developing the programme. Such additional funds would enable us to:

- Develop appropriate web based materials
- Train staff to facilitate blended learning
- Subsidise the initial cohorts of learners in terms of fees, travel, childcare, technical support and even hardware
- Market, monitor and fully evaluate the work

Fortunately, the bid was successful and we are about to embark on the training and development stage of the programme with a view to running an induction event in early summer with the full programme set to commence in the autumn.

The remainder of this paper will therefore focus on the development of this 'work in progress'.

Significant issues will certainly include:

Developing staff expertise sufficient to deliver learning in a, for them, entirely novel way. Key questions here will certainly include the level of technical expertise that they feel they need, the question of e pedagogy, the extent to which critical thought and analysis can be assessed on line, and the demands of 'e moderating' or 'e tutoring'. Some staff will certainly be enrolled on 'Embedding Learning Technologies' a mainly online Masters programme at the University of Plymouth on the basis that the experience of learning on line themselves will give them an insight into the issues that their learners might themselves encounter.

The experiences of building a team drawn from both conventional higher education and 'voluntary sector' experts from a training background. While this will be essential to the success of the project if the learners are to receive an appropriate blend of generic and specialised instruction, it is something of a rarity in education in the UK. Experience to date shows that such collaboration can be very fruitful, but equally it throws up a number of issues around planning cycles, ideas of quality, levels of achievement etc

Introducing or inducting learners into what will be, for them, a wholly new form of learning. It is clearly evident from the literature that the quality of the learner's initial contact with the technology has a major impact on subsequent motivation and achievement.

Agreeing a solution to the more technical debate over the most appropriate 'online learning' environment for learners with limited technical skills and equally limited hardware. Current thinking is that it would be better to ensure easy access through using some simple website based HTML model even if this at the expense of the level of interactivity offered by the proprietary brands such as WebCT, Blackboard etc.

The Potential of Virtual Reality to Improve Education About Psychosis

Dr Jennifer Tichon,

Virtual Reality (VR) techniques are increasingly being used in healthcare education. A project at the University of Queensland constructed a number of three dimensional demonstration models of the phenomena seen in psychosis. Symptoms of psychosis reproduced include delusions, hallucinations and thought disorder. Auditory hallucinations have also been included, consisting of voices ranging from muffled whispers to a cacophony of voices. This paper reports on the methods and tools currently being utilized to educate psychiatry and mental health students about schizophrenia and psychosis, the expectations of both Lecturers and students of introducing VR in the classroom in terms of potential increased understanding of psychosis and the software program development to date. The next phase of the research examining the impact of VR on learning and pedagogy in the topic of schizophrenia has commenced. Preliminary results indicate the use of Virtual Reality in healthcare education has enormous potential significance in psychiatry and other mental health teaching programs.

Introduction

The recent success of the film "A Beautiful Mind" has highlighted schizophrenia, a debilitating mental illness which affects 1–2% of the population at some point in their lives. It is estimated 12–16% of hospital beds in Australia are taken up with patients with schizophrenia. Tragically, suicide is more common among sufferers of this illness, which often strikes people in their prime. At present, patients with schizophrenia have to describe their symptoms to their therapists and there is no objective way for therapists to evaluate these experiences. Many patients suffer from various forms of hallucinations, auditory and visual, and these can often be extremely terrifying for them. Patients may feel misunderstood and find it difficult to communicate the exact nature of their psychosis. Similarly, therapists find it extremely difficulty to learn and to fully understand this illness because they themselves have no personal experience with it. Pivotal to professional understanding are the methods currently being used to teach about schizophrenia in higher education institutions. Are the methods and tools currently being utilized to educate mental health students about schizophrenia sufficiently adequate to provide students with a true understanding of what these patients experience and does the use of virtual reality in the classroom have the potential to improve this?

Virtual Reality and Health Care

Recent developments in the use of Virtual Reality (VR) to help improve patient care in the form of advanced educational tools and therapeutic options have shown to be highly successful (Zajtchuk & Satava, 1997). VR techniques, involving 3-dimensional imaging and surround sound, are increasingly being used in healthcare education and research. For example, VR has been used to perform surgery-related applications and to provide medical education in training people to deal with catastrophic emergencies such as earthquakes, plane crashes, fires and so on (Waterworth, 1999). VR has also been used to treat phobias such as fear of heights, flying, spiders and treatment of post-traumatic stress disorder (Hodges et al., 2001). Another related area is using VR to simulate the effects of stroke (UMEA University VR Lab, 1999). The benefit of simulating the difficulties faced by stroke patients with everyday physical tasks such as, getting a glass of water or wearing a shirt, is the facilitation of a greater understanding and empathy for caregivers or other helpers who may not be fully aware of some of the difficulties recovering stroke patients go through.

Current Teaching Methods in the Field of Schizophrenia

VR has not previously been used to teach in the field of schizophrenia. The teaching methods and/or tools currently being utilized to educate psychiatry and psychology students about schizophrenia and psychosis in many universities and training centers consist predominantly of abnormal psychology textbooks. The specific aim for many of these textbooks is to provide students with a clear understanding of the history, the etiology and the various diagnostic classifications used for schizophrenia and psychosis. For example, many textbooks devote at least a section to demonstrate an example of the diagnostic criteria for schizophrenia used in the DSM-IV (Diagnostic and statistical manual of mental disorders- Fourth edition) (American Psychiatric Association, 2000).

Many of the textbooks examined included anecdotal case reports of patients' experiences with schizophrenia and psychosis. Many of these case reports provide a personal account of what the patients themselves experience during their illness. These case studies are an attempt to engage students to feel and to experience patients' symptoms at a more basic level (Beumont and Hampshire, 1989; Oltmanns and Emery, 2001; Rosenham and Seligman, 1984; Van Hasselt and Hersen, 2001) and acknowledge the importance of student's '*experiencing*' an illness. However, despite this, there are limited availability of teaching tools that include the use of multi-media to facilitate experiential learning.

Experiential Learning

Experiential learning, prior to the advent of advanced technologies, often took the simple form of role-play. In essence, students were required to "step into the patients' shoes" and act out the part of a person with schizophrenia. Role-play functions not only as a teaching tool but also provides a vehicle for students to experience as close as possible what it feels like to have schizophrenia and/or psychosis. A program designed to evaluate a training program for occupational therapy students found that the majority of students responded most favorably to the field experience and role-play phase of the curriculum (Patterson & Davidshofer, 1972). Role-play has long had important implications for educational planners. The need is to design curriculums that not only provide students with the required intellectual knowledge on a specific subject but to also provide as much experiential learning as possible.

Unfortunately, most of the abnormal psychology textbooks seldom discuss or use role-play as part of the text exercises. Many include numerous reference guides for students and lecturers including self -help books for patients. These books focus on the psychological experiences of patients with schizophrenia and the impact this has on patients' family and friends (Hurlburt, 1989; Sattler, et al., 1998). However, although detailed these texts do not provide any opportunity for students to personally *experience* the illness. Without more direct encounters can students ever fully understand the auditory and visual hallucinations experienced by patients with schizophrenia?

Virtual Reality and Teaching About Schizophrenia

An important recommendation for students in the mental health profession suggests that, in addition to the traditional lecture and textbook mode of teaching, educational planners must investigate other less traditional methods of teaching such as multi-media to increase student's experience of an illness (MacPherson & Keppell, 1998; Teevan & Gabel, 1978). VR has been used successfully in education to provide a more interactive learning experience for students (MacPherson & Keppe4ll, 1998).

The use of VR can provide students with first hand knowledge of what hallucinations "feel" like. It is expected the use of the specifically designed VR software will provide a greater understanding on the exact nature of psychosis and will develop in students a greater sense of empathy for the mentally ill, leading to greater positive attitudes. The research is exploring the reactions and responses from lecturers and students about the use, the effect and the problems using VR as part of the teaching technique in an educational setting.

Interviews with lecturers have been conducted and surveys have been distributed to students in two postgraduate and three undergraduate Australian mental health training programs. The interviews and surveys occur in two phases:

Phase 1: Pre VR

Prior to the implementation of the VR software the focus is on student/lecturer expectations of introducing VR in the classroom, in terms of potential increased understanding of psychosis and improved educational outcomes. Other questions relate to usability of the application and interaction design.

Phase 2: Post VR

Post the implementation of the VR software the focus is evaluation at lecturer and student levels. A close examination and documentation of how lecturers and students adapt, use and report on VR will contribute to our understanding of the effectiveness of this innovation. The data gathered during the post-VR phase will be compared to data gathered in the pre-VR phase of the research with the aim of demonstrating the implications of VR technology for university education.

The Software

As this research is highly technical from the information technology perspective, yet qualitative from a clinical viewpoint, it is very unusual and there are few other groups, if any, working worldwide in this area. An initial pilot program demonstrated that the clinical and technical skills are available to create the various models of the phenomena of psychosis. A model of an everyday environment, in this case, a living room, was developed. This room contains standard furniture, including a sofa, coffee table, dining table, chairs, and bookshelf, as well as a number of objects which tend to exacerbate patients' symptoms, such as TV, radio, and pictures.

In this model, a small number of hallucinations were modelled to demonstrate the concept of virtual psychosis. Techniques such as morphing and 3D enhancement of objects are used to reflect the types of illusions that patients with psychosis might experience. Visual illusions modelled include the morphing of the face in the portrait frame into another person and back again, modelling the feeling of claustrophobia, caused by the walls of the room appearing to contract, and the TV and radio switching on and off of their own accord. Patients have been employed as consultants on the project and ultimately a "library" of psychotic symptoms, built from the patients' perspective, will be created. The Living Room Model can be viewed and interacted with through the curved screen immersive environment of the ViSAC laboratory at the University of Queensland.

The software development is being carried out using the Vega software environment for real-time simulation and virtual reality applications. Virtual Reality Modeling Language (VRML) was designed to allow 3D "worlds" to be delivered over the World Wide Web (www). VRML files are analogous to Hypertext Markup Language (HTML) files in that they are standard text files which are interpreted by browsers. Like HTML, VRML has been designed to be platform independent and to work over low bandwidth connections. VRML files describes a 3D space, or 'world' and using a VRML browser the user can explore this world, zooming in and out, moving around and interacting with the virtual environment. This allows fairly complex 3D graphics to be transmitted across networks without the very high bandwidth that would be necessary if the files were transmitted as standard graphic files. The aim is to use VRML to web enable these scenarios so they can be accessed easily and efficiently over the web.

Conclusion

The high quality infrastructure available at the University of Queensland provides a unique opportunity in Australia to undertake this collaborative project. The project has enormous potential significance in mental health e-learn field.

E-Learning that Adapts to the Learner

Introduction

Most learners and educators would agree that the ideal educational environment has at its core one-on-one teaching that is closely customized to the needs of the individual learner. In all current educational sectors, one-on-one teaching is very rare. Learners must make-do with instruction geared toward the average student or the perceived norm. This leads to a large segment of marginalized students who do not fit the norm. They may differ in their background knowledge, level of understanding of the topic, learning outcome goals, learning approach, learning skills and accessibility needs.

One of the opportunities afforded by dynamic web technologies and broadband networks is the ability to serve educational content and environments that are tailored to the individual learner or learning context and thereby deliver the approximation of one-on-one teaching. Broadband networks open the communication channel in both directions, enabling educational servers that can respond to each individual learner and learning context in a timely manner. Thus the on-line educational environment can be responsive to a number of learner needs and preferences. These preferences can be general learning preferences or preferences related to a particular learning session.

Personal Preferences

A learner may have individual needs or preferences regarding a variety of parameters. Some of these are:

1. Styling preferences: This includes the information layout, the font size, and the colours used on the page. For someone with low vision this may make the difference between illegible and legible content.
2. Depth of Navigation Tree: Some learners prefer to have all possible links shown on one page while others prefer to have top level links with lower level links appearing on subsequent linked-to pages.
3. Classification or Sorting Preferences: Mail archives frequently offer the choice of sorting by sender, date, subject, priority level among others. Other sorting criteria could include level of difficulty, match with expressed learning outcome goals and teaching style.
4. Access Requirements: Learners with disabilities frequently require alternative access strategies such as screen reading for people who blind, or on-screen keyboards for people who cannot use a mouse or keyboard. The preferences can address both the type of alternative access technology and the preference settings for the access technology (e.g., voice rate and pitch, key size and spacing)
5. Equivalent Content Requirements: Learners with sensory impairments require streaming auditory or visual information to be provided in another modality but synchronized to the primary content. The system can provide the requested type of equivalent content (captioning, ASL, video description) delivered according to the user's preference (styling, layout, reading level, etc.).
6. Testing Equivalents: Learners with disabilities or language constraints are unable to answer certain kinds of test questions. These individuals require test questions in an accessible modality that are equivalent in the skills or knowledge being tested.

7. Language: The learner may have an alternative language requirement, or may wish the content to be displayed in two languages to support better comprehension.
8. Content Density: Some learners prefer to master on overview of the content and then learn the specifics of each subtopic, while others prefer to move sequentially through all the details of the topic.
9. Content Views (Image intensive, text intensive): Some learners are best supported through visual illustrations of the content, while graphics and images may be distracting or inaccessible to other learners.
10. Learner Scaffolding types: Learners require individualized learner supports. Some learners benefit from readily available definitions of terms, others benefit from exercises or illustrations of concepts, while still others require peer interaction to fully integrate a concept.

Preferences that relate to a specific learning session include:

1. Learner Outcome Goals: Learners approach learning content with different outcome goals. A system that organizes content in support of the outcome goal and assists the user in tracking their progression toward the goal may assist in achieving the learning outcome.
2. Topic Exclusions: In some instances, less is more. A filter to exclude content that is not of interest or is already learned may help the learner to focus on the target content.
3. Placeholders, Annotation and Knowledge Review: Progression through specific learning content would be supported by allowing the learner to create placeholders, personal annotations and by creating a synopsis or review of the previous session.
4. Facilitation of Communities of Interest. Learners vary regarding their preference for the frequency and timing of peer interaction in support of learning.

Interoperability Standards

Several standards or common specification efforts are underway to capture and communicate learner or user preferences for learning content and user interfaces. Among these is the IMS Learner Information Package (LIP) specification. The IMS Global Learning Project Accessibility Working Group is attempting to extend and harmonize these schemas into a common specification that will form part of LIP specification. This new extended specification will include elements that express learner preferences that relate to accessibility needs and personal learning approach preferences.

Agents that Act Upon Preferences

Once the learner has expressed his or her preferences or needs, either by using a preference tool, or an integrated preference dialogue within a learning management environment, there are a number of agents that can act upon the stated preferences. The Learning Management System or browser can adapt the user interface, the presentation of the content, and the presentation of the content structure. The learning object repository can use the preference as a guide to refine and constrain the learning objects retrieved and the aggregation of the learning objects. For example a video learning object may be aggregated with a synchronized text caption file as well as an illustrative exercise for a learner who is deaf or with a structured outline in text for a learner who prefers this navigational aid.

Authoring and Instructional Design Support

A core assumption of learner-centric courseware delivery, whether it is simply providing device independent information or full learning-style accommodation, is that the content delivery medium can be independent of the content while still achieving a consistent learning outcome. This requires a dramatic shift in instructional design that most educators are not cognizant of when designing learning material for the web. It requires a deconstruction of teaching and a new set of authoring tools and supports. Most web-authoring tool features concentrate on the specific visual presentation of the material. They do not assist the author in extracting the content and structure and determining whether it transforms gracefully while still retaining the intended learning message. Most educators devote a great deal of attention to designing the presentation of the learning content at the expense of refining the content and its structure. New instructional design methodologies and authoring tools are needed to support the type of adaptability envisioned here.

Application 1

The Adaptive Technology Resource Centre of the University of Toronto and eight partner institutions have developed a learning environment that allows the adaptive personalization of video based curriculum. The Barrierfree project includes a process, a set of tools, and teaching practices that allow the creation and delivery of inclusive, video-based, interactive learning content. The Barrierfree environment gives each learner the opportunity to access the learner scaffolding they require and to navigate through the content in a fashion that best suits their learning needs. Tools and processes developed include: authoring tools that support educators in creating accessible content; a preference wizard that allows learners to specify their learning preferences; a player/browser that responds to the learner preferences and allows flexible navigation through the content, and a repository that serves content according to the learner preferences.

Application 2

In another implementation of the Personal Preference Specification the ATRC is investigating the implementation of the specification in personal web portal technologies. Thus the personal preference schema will be used to also configure the navigation tools, content organization, content presentation, personal bookmarks, and the content retrieval algorithm within a portal. This will be implemented using uPortal, an open source portal initiative and used in post-secondary and government portals.

Conclusion

We may finally have available to us the tools needed to create learner-centric educational environments. This development is critical to any learner or learning context that does not fit the model of the typical student and their environment. This includes learners with disabilities, learners with unique learning styles, learners using atypical client devices, students learning in unusual environments and learners approaching the topic from different perspectives or knowledge backgrounds. In order to achieve this level of adaptability we need to create tools and system architectures that allow interface and content transformation, but more importantly we need to dramatically shift our approach to teaching.

Using Electronic Portfolios in Teacher Performance Assessment

Burcu Tunca
The George Washington University
btunca@gwu.edu

Abstract: Portfolios have been used for a long time in various fields especially in graphic arts to show the quality of work. In early 1990s educators adopted portfolios for determining grades and to show students' performance to parents. In late 1990s portfolios have become powerful tools for teacher professional development. In late 90s format of portfolios has changed from paper form to electronic form which gives opportunity for more creativity and portability. This paper will be talking about using digital portfolios in teacher performance assessment, suggesting ways of using electronic portfolios in teacher performance assessment and showing some examples of electronic digital portfolios prepared by teachers.

Introduction

A hundred years ago, in order to become a teacher, morality and some level of literacy was enough. In today's age, besides having morality and good character, good education is vital since teacher performance has gained a lot of importance and become significant in institutions. Today's teachers are expected to be highly competent in their content and understand their society. They also have to be competent in pedagogy, technology and subjects to be taught. Moreover, teachers have to meet the state standards as well. Based on the standards, teachers have to know the expected learner outcomes, meet the expected level of teaching performance as well as meet the vision of the institution that they perform at.

In order to find out if teachers meet the standards, institutions design teacher performance assessments. The focus of these performance assessments is to see if teachers are up to date. In order to be up to date, teachers have to keep up with technology and with the latest trends in their fields. Another focus is to see if teachers have improved themselves when compared to previous years and if they can implement the new information and techniques that are introduced. In order to make sure that teachers perform at their utmost, institutions organize formal courses, seminars, workshops, and send them to degree programs. Managers at these institutions also make sure that teachers reflect on their day-to-day work and learn from these experiences as well. Besides these professional development activities, organizations may use some traditional methods like class observations, checking lesson plans and use course evaluations filled in by students.

A new method for teacher performance assessment: Using electronic portfolios

Portfolios have been used for a long time in various fields especially in graphic arts to show the quality of work (Campbell, 2000). In early 1990s, educators adopted portfolios for determining grades and to show students' performance to their parents (Linn & Gronlound, 2000). In late 1990s, portfolios have become powerful tools for teacher professional development (Wolf, 1999; Burke, 1997). In education, portfolio can be defined as a purposeful collection of teacher work that exhibits his/her efforts, progress and achievements in one or more areas (Barrett, 1990). Portfolios give a richer picture of teacher work than can be gained from more traditional, objective forms of assessment. Traditional portfolios are stored in three ring binders or folders with physical dividers between sections. A portfolio consists of: teaching philosophy, classroom management philosophy (optional), a resume, curriculum plans, student evaluations, administrative evaluations, meetings and workshops log, observation reports, peer critiques, professional development plans, professional projects, research papers, self assessment experiences teacher prepared materials and some artifacts. The artifacts can be: anecdotal records, sample lesson plans, video taped class teaching, test samples, awards and certificates, pictures and photographs, sample student portfolios. The items above can be eliminated according to the purpose of the portfolio and the audience that is going to evaluate it.

Electronic Portfolios:

An electronic portfolio consists of technologies and that allow the portfolio developer to collect and organize artifacts in many media types like audio, video, graphics and text (Barrett, 2000). According to Barrett, "what differentiates an electronic portfolio from a digital scrapbook or an online resume is the organization of the portfolio around a set of standards or learning goals, plus the learner's reflections, both on their achievement of the standards, and the rationale for selecting specific artifacts, as well as an overall reflection on the portfolio as a whole (2000)." There are also technical advantages of creating electronic portfolios. It is easy to store and allows easy access to information as well as being portable and having a long shelf life. It is possible to have multiple copies at a very low cost and can be more presentable as it consists of multimedia and hypertexts that can be linked to standards if desired.

Barret, mentions about some important reasons for creating about electronic portfolios (1998). She states that documents are already created on computers and then printed to form paper based portfolios. The use of hypertext links allows clear connections between standards and portfolio artifacts. It has been observed that creating electronic portfolios can develop skills in using multimedia technology. It can be more motivating and easier to manage the portfolio development process. When all these advantages are taken into consideration, using electronic portfolios in teacher performance assessment sounds radical but very effective.

In order to use electronic portfolios as a tool to assess teacher performance, an implementation plan needs to be developed to give a framework to the teachers so that they can use as a guide in the process of developing their own portfolios. In this type of a portfolio, teachers need to include *samples of work* as a general outline in which they demonstrate *personal growth*, *professional growth* and attention to *various instructional initiatives*. These key words describe the parts of the process and portfolio products. In the process, teachers select the contents as well as the best means of presentation (Kimeldorf, 2000)

After selecting the artifacts and deciding on the means of presentation, teachers have to arrange the design and get assistance from more technology savvy colleagues or staff. Once institutions start implement assessing teachers' performance using electronic portfolios, both the teachers and the institutions will see the benefits to it. They will see that electronic portfolios are a more objective way of assessing teacher performance as video taped teaching can be assessed by various people and the ease of documentation. Moreover, they are great tools to see the personal development and gaps which can lead in planning professional development activites.

New Roles for Teachers and Learners in Higher Education

JoAnn C. Ullery
South Dakota State University
Information Technology Services
Wecota 211, PO Box 506A, Brookings, SD 57007
605-688-4682
JoAnn_Ullery@sdstate.edu

Abstract: The integration of technology in classrooms has had a positive impact on student achievement (Valdez and others 1999). But an investment of time and resources for faculty is necessary to move technology from a part-time tool to an active tool, fully integrated into the curriculum. Also, in order to provide technology in the classroom, educators must receive professional staff training on how to effectively use technology. This paper discusses the use of the web as a professional source of development and curriculum materials, and how to integrate technology into classrooms to promote learning. This session will provide suggestions for collaborative learning and group problem solving in the classroom, "just-in-time" learning, and how educators can become facilitators and coaches to students.

Introduction

Technology in Higher Education

Clark Kerr described a modern university as "a series of individual faculty entrepreneurs held together by a common grievance over parking." This humorous observation highlights a theme regarding technology in higher education in that often the only thing that will unite a diverse group of educators is a complaint over a commonly valued resource that is in short supply. At South Dakota State University we manage these valued resources and experience these complaints at a loud volume from arguments between faculty who embrace technology to those who fear technology threatens the courses they teach face-to-face.

First, in order to manage our information technology resources at SDSU and promote a shared institutional vision and sustained communication to our faculty at SDSU, our Associate Vice President of Academic Affairs was appointed as our Chief Information Technology Officer with all technology reporting to him. Even though strategic planning is uncomfortably close to an oxymoron with the life cycle for technology approximately 18 months, a strategic plan for technology was created that is tied to the primary mission and goals of the college or university. Those goals have clear objectives were agreed upon by the leadership of the campus community.

Invest in Information Technology

Academics were skeptical of the typewriter, the telephone, and the television. Each of these technologies required enormous capital investments, and we now need to invest in computer technology. Colleges and universities cannot afford to cut that which is critical to their future success if they want to continue to be relevant to students and the culture at large. Significant investments will be necessary in hardware and infrastructure if educational technology is to be effectively utilized.

SDSU's strategic plan included a major renovation ($1.5 million) to its campus network to prepare our core infrastructure for research, library, e-learning, and administrative services. The old ATM network was phased out and replaced with a Gigabit Ethernet network we enjoy today. SDSU also participates in a major Internet2 initiative through a grant from the National Science Foundation. Internet2 promises to enhance teaching and learning as faculty member's use its capabilities in Web-based courses.

Information Technology in Support of Teaching and Learning

Build it and they will come. Well, SDSU built the network infrastructure and today's generation of children have indeed arrived. These children have grown up "surfing the net", playing video games, chatting with friends, doing research, and applying to colleges and universities online and expect to use the Internet in all facets of their lives. And the most dramatic change is yet to come: it is our future students, whose elementary and middle-school children who have always had computers in their lives will enter our classrooms with expectations that will dwarf the technological capabilities we have today.

Consequently, institutions that ignore the potential for technology in teaching and learning will be left behind as students raised in a digital world enter the university with expectations of an interactive, e-learning culture. Students today are indeed driving the change in higher education and at a speed that is challenging universities to organize their faculty and develop courses online, hoping to cash in on attractive economic opportunities for "e-commerce".

Where to Begin?

It begins with professional development for faculty and educators. What I have learned in my years of working with and teaching faculty is that single meeting workshops are NOT effective. Change requires sustained faculty development over time with support as defined by the situation. The Preparing Tomorrow's Teachers to Use Technology (PT3) grants program, funded by the U.S. Department of Education, has supported various configurations of professional development at the university level. Some of the reportedly successful models include:

- **Technology Tuesdays** for workshops
- **Mentors** – SDSU has a Student Technology Fellow program
- **Model Classrooms** – A model classroom to use as a staff development center
- **Collaboration** with Universities.

Faculty need to commit to lifelong learning and that includes learning the necessary technological skills for academic productivity. Institutions need to provide faculty with incentives, expertise, resources, and human support, for them to feel confident with technology. It only makes sense that before technology can significantly improve learning, teachers must first be competent with the technology applications that facilitate their work and support student learning.

The university also needs to take a leadership role and provide faculty with he assistance of technology coordinators in their department. A coordinator can play an important role in demonstrating effective technologies in the classroom as well as coaching faculty in the effective use of technology or providing assistance in designing their online courses. When educators have questions or problems, they need immediate access or "just-in-time" assistance for effective use and application. Faculty want to be "coached" or receive personal assistance as they prepare class lessons to their specific situations. Also, faculty need to attend conferences, have periods of planning time, have staff development days, and periods when teachers can work together or brainstorm teaching and learning using technology.

Online Distance Learning

Online Distance learning has been available for many years, in different formats and now represents about 12% of higher education enrollments (Green, 1998). The California Distance Learning Project (1997) defines the following elements as key to distance learning:

- The separation of teacher and learner during at least a majority of the instructional process
- Connection through educational media
- Volitional control of the learning process resting with the learner

In 2002, it is projected that over 2.2 million "students" will participate in a distance learning course representing a 33% compound annual growth rate. (Source: IDC) The reasons for its growth include availability of particular courses, financial and time support for extended learning driven by the work environment, and the need for flexibility to support more complex lives of students and faculty. So let's discuss the specifics of an online course.

More than using PowerPoint as a delivery tool or WebCT to host a course online, the integration of technology in teaching and learning can be a powerful tool for both teachers and learners. The International Society for Technology in Education (ISTE) is an organization which promotes appropriate uses of technology to support and improve learning, teaching, and administration. They have several excellent publications, *Guidelines for the Evaluation of Instructional Technology Resources* and *National Educational Technology Standards for Teachers*. You can order it online at www.iste.org . Using the tools and resources available from ISTE will facilitate learning, and provide many suggestions, ideas, and forms for creating online courses. One method I used to assist beginning faculty to use technology was to help them move overhead transparencies to PowerPoint slides or taught them to create a course Web site. When faculty members become comfortable with this technological tool, are willing to have students assist and provide feedback, or offer new ways of doing things, e-learning will take place.

The syllabus is also a good place to start as it represents the contract between the professor and the student. It is often the most underdeveloped piece of writing a professor generates. In an era of assessment and accountability, the syllabus can provide both the cognitive map for the student and the qualitative anchor for assessment criteria (Pallof & Pratt, 1999). At a minimum the syllabus should contain course information, instructor information, course descriptions, goals and objectives, required readings, instructional methods, a calendar, classroom policies with links to university policies, grading criteria and standards, assignments tied to calendar dates, and available support services.

Class Web Site

When teaching and learning leave the classroom it is up to the instructor to create a "class in cyberspace" by posting the goals, objectives, and expected outcomes of the course, initial guidelines for participation, thoughts and questions to initiate discussion and assignments to be completed individually and/or collaboratively. Then the instructor can take a deep breath while the learners move forward with discussion and collaboration, intervening to ask questions or steer a discussion back on track.

Yes, it does take a large investment in time to produce a course Web site, but that investment, can diminish with assistance from the IT department, a faculty development center, or using FrontPage or Claris Home Page to create a Web site. Benefits include accessibility to course resources 24/7. Faculty can address the multiple learning styles of students and encourage even the less overt students to participate. Additionally, all class interaction, inside and outside of the cyber classroom, supports the development of a learning community based on the course content.

More sophisticated enhancements to a course Web site include a place for students to post their work, posted PowerPoint notes or other class materials, posting electronic quizzes, and/or using Course Management Software (CMS) such as WebCT or Blackboard that offer customization, file management, communication tools, assessment tools, and general course management. Web-based courses offer many challenges and students and faculty must accept the opportunities to become leaders and learners in facilitating change in the in the field of education.

Technical support must be available to help students log on, use the software, upload and download files, use audio and video clips, as well as help faculty who are having their own technical problems. Ideally, faculty or staff should always check for problems prior to the start of a course. Institutions, like their faculty, must engage in good planning in the delivery of online programs and courses and be willing to provide the level of support necessary to make the programs and courses work. Anything less results in frustration on the part of both students and faculty, as well as a loss of confidence in the process of distance learning on the part of both (Palloff & Pratt, 1999).

The Specifics of an Online Course

Communities – the Essence of an Online Course

Carolyn Shaffer and Kristin Anundsen (1993) talk about our human yearning for a sense of belonging, kinship, and connection to a greater purpose. Changes in the makeup of our families, neighborhoods, and towns have increased that longing, as we are not as easily able to identify with something we can call a community. Our communities today are formed around issues of identity and shared values; they are not place-based (Palloff, 1996).

So what does community have to do with online learning? Palloff and Pratt (1999) contend that in distance education, attention needs to be paid to the developing sense of community within the group of participants in order for the learning process to be successful. The learning community is the vehicle through which learning occurs online. An instructor can begin a course by posting introductions, encouraging students to look for common areas of interest, or create a "virtual café" or "Cybercafe" for students to discuss personal issues with others in the class. Also, in order to form a community of learners, everyone must participate and this requirement must be outlined in the syllabus.

During my presentation I will list specific web sites and provide handouts to guide you in building an online course, how to promote collaborative learning, suggestions for springboards to learning, developing assignments, transformative learning, opportunities to encourage reflection, and assessment and evaluation.

The Role of the Learner

Let's not forget the learner and their role. The successful learner needs to be actively engaged in learning, be responsible for actively seeking solutions to problems, view problems and questions from a number of perspectives, question assumptions, be able to critically evaluate their own learning style, gather additional resources that are pertinent to the area under study, collaborate or work together, share resources, generate a bibliography of readings, post other materials of interest, collaboratively prepare a report or work on a joint project and provide meaningful feedback to others. Also, instructors who are teaching similar courses, either at the same university, or different universities around the world, can encourage discussion among participants in those classes.

Conclusion

Higher education has been under considerable scrutiny lately and has received its share of criticism regarding technology in the classroom. Our educational systems were architected to deal with survival in a mechanistic society, where we taught people to follow instructions – and work on farms or in factories. The school based on the archaic factory model doesn't prepare students because the relevant skills and attributes that students need to be successful in this century and the next are not being addressed (Caine&Caine, 1994 p.15).

In today's knowledge-based economy, society needs people who can think critically and strategically to solve problems. Individuals must learn in a rapidly changing environment, and build knowledge taken from new sources and different perspectives. Today we must understand systems in diverse context, and collaborate locally and around the globe using tools like the Internet (Reich, 1995; Merrill Lynch, 1999).

At South Dakota State University we embrace information technology and all that it can do for us, but more important, we are devoting a great deal of our time and resources to using it to transform the way we teach and the way our students learn.

The Poor Man's Eyetracker Tool of ActiveMath

Carsten Ullrich and Erica Melis
DFKI Saarbrücken, Germany
cullrich—melis@dfki.de

Abstract

We address the problem of tracking some of the student's activities in an e-learning system to obtain data that can be used to diagnose and to react appropriately to the student's actions. In order to find out how long a student deals with a single paragraph/text-unit on a web-page we developed a poor man's eye tracker (PME) software, DFKeye. This tool can be configured for several appearances. The usage of a PME avoids the drawbacks of hardware eyetrackers that are not usable in an everyday learning environment.

1 Motivation

In empirical psychology, eyetrackers are a common tool for tracking the user's attention and for investigating design and usability features of computational systems and their user interfaces, see, e.g., [3]. These eyetracker facilities can, however, only be used in a laboratory, are difficult to adjust, and impose restrictions on the user. Therefore, their usage outside the lab, e.g., in everyday e-learning or other non-experimental activities, is impractical. Furthermore, the very detailed information of the user's visual focus which a hardware eyetracker provides is even too detailed for e-learning diagnosis purposes and has to be abstracted.

Nevertheless, for a diagnosis in an e-learning system, information about the user is required to appropriately determine the system's user-adaptive behavior and its suggestions. This information can partly be deduced or estimated from the student's learning activities. Especially the learner's performance in exercises and her navigation can be evaluated to estimate her capabilities without too much intrusion. Therefore, many intelligent systems use those activities to update the user model.

For reading and watching activities detailed information is rarely handled; some approaches measure the reading time for complete pages. These times can be compared to dynamically calculated optimal reading times, see for instance [5]. However, as the taken time refers to a complete page, it does not allow any conclusion about *parts* of a page, e.g., whether/which parts of the text have been skipped. Another disadvantage is the static nature of the observation. That is, when the student has worked on a page and goes to the cafeteria to relax before she resumes learning, then there is no way to distinguish the actual reading time from her time in the cafeteria.

We know of only one attempt that uses a finer grained measurement. That is Conati's masking interface that makes time taking for single problem solving steps possible by covering or fading the text of the steps [2]. Conati's interface is, however, implemented inside the Andes system rather than stand-alone and is not browser-based, and hence not reusable. Moreover, it has the disadvantage of hiding all the text that is outside the direct focus of attention. Since all the other steps in the worked-out example are invisible, the student no longer has an overview on the structure of the solution. The cafeteria problem arises, too.

We designed and implemented a PME that serves the learning environment ACTIVEMATH [4]. ACTIVEMATH is a generic web-based learning environment that dynamically generates interactive (mathematical) courses adapted to the student's goals, preferences, capabilities, and knowledge. The content is represented in an semantic `XML`-based format. It consists of units such as definition, example, exercise, or remark. For each user, the appropriate content is retrieved from a knowledge base and the course is generated individually according to pedagogical rules. The course is rendered to `HTML` and presented to the user via a standard web-browser. The student's interactions are used to update the user model and analyzed by a next-best suggestion mechanism that provides the user with hints about which actions to take next. The quality of the user modeling and the suggestions strongly depend on their input, that is the user's behavior. The more accurate it is tracked, the higher the quality.

Therefore, we needed and designed a browser-based time tracking facility that

- can provide the time spent on a *single* unit of a `HTML`-page rather than on the page,
- acts as a *stand-alone* module and communicates with other modules, e.g., with the user model;
- does not hide or change but *keeps and highlights the structure* of the example or document at hand,
- is *parameterizable* because different users might react differently to different PMEs, and finally
- is *dynamic* and notices when the user does not pay attention to the learning document.

To the best of our knowledge such a tool does not exist yet. In the remainder of this paper we describe this tool.

2 Poor Man's Eyetracker DFKeye

Human-computer interaction research reports experiences [1] on that and how the mouse movement follows the eye movements. Therefore, it is natural (rather than an additional effort) to expect from the learner to move the mouse as she goes along with reading a document such that the mouse location indicates the current focus of attention. However, some student do not move the mouse in an appropriate fashion and thus have to be softly forced to do so.

The information that can be expected from such a mouse movement is less detailed than the information of an eyetracker or, put differently, at a more abstract level, namely the order in which the elements have been focused and the duration of the focus. This does not harm its envisioned applications in e-learning, however.

The ability to measure the time a student takes to deal with a text-unit requires a structure of the web-presentation. This structure naturally arises from ACTIVEMATH's underlying knowledge representation that represents the content not as complete pages but as single paragraphs/units.

When ACTIVEMATH displays a page, the PME makes the text contained within a unit (slightly) unreadable. Three different variants have been implemented: *cover* (puts a black cover over the text), *fade* (changes the font color to nearly match the background color), and *zoom* (changes the font size to miniscule). If the learner focuses a unit by moving the mouse pointer on it, the PME unhides its text and starts a timer. If a unit looses the focus as the mouse pointer is moved away from it, its timer is stopped and its value is send to the DFKeye web-server.

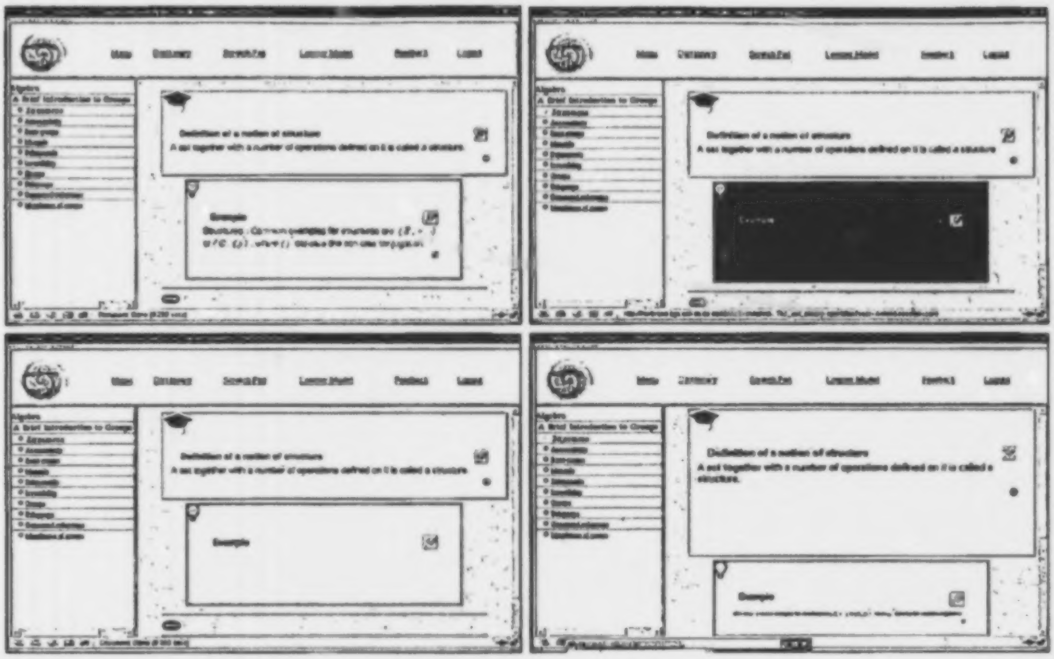

Figure 1: ACTIVEMATH eyetracker variants: none (top left), cover (top right), fade (bottom left) and zoom (bottom right)

The delay between touching the unit and focusing it is parameterizable (per default 0.7 seconds). We have chosen to not change the focus immediately as we wanted to minimize the amount of irrelevant data: often the learner moves from one unit to another one that is not directly adjacent. In this case she doe not focus on in-between units for which therefore no time information is taken. To tackle the cafeteria problem, a unit automatically looses the focus after a parameterizable delay (per default 30 seconds). If the student moves the mouse again, the unit regains the focus. Both delay times are not yet empirically confirmed.

Let's have a look at the example in Figure 1. It shows the same page in ACTIVEMATH in the different PME variants. The visual separation of the paragraphs reflects the structured representation of the content: Each paragraph corresponds to a proper unit. The learner focuses the upper unit, the definition of a mathematical concept. if no eyetracker is used, the complete page is readable (top left). Otherwise the text in the example (the paragraph below) is covered, faded (only faintly visible in the figure), or shrunken, resp. The structure of the page remains visible, though. The icon and the color scheme clearly indicate the type of a unit and its title stays readable.

Thanks to the PME, ACTIVEMATH can analyze and react to the learner's reading behavior. For instance, if the learner focuses an example over and over again and then solves an exercise correctly, ACTIVEMATH can assume that she has studied the example throughoutly and the user model strongly increases the user's application level of the concept the exercise is for. Otherwise, if the learner never touches the example and subsequently performs poorly on the exercise, ACTIVEMATH's suggestion mechanism can invite her to look at the skipped example.

Technical Realization ACTIVEMATH integrates the PME as a Javascript application. It

BEST COPY AVAILABLE

mainly uses `onMouseOver/onMouseOut` event handlers on `HTML div` elements that catch the mouse movements. The time information is send to a servlet (java server application) immediately after a unit looses the focus. The servlet sends the data to the interested modules such as the user model and a suggestion mechanism.

The PME was implemented in strict conformance to the W3C standards, and is usable in all W3C-compliant browsers (Mozilla, Netscape6) and in IE5. We implemented a PME-kit that can be easily integrated into existing web-based systems.

3 Conclusion

Although the information that a PME provides is less detailed than the information of an eyetracker, this does not harm its application in e-learning because the less detailed information corresponds to an abstraction of the common eyetracker information that is useful for e-learning diagnosis.

The tool can be used for other purposes for which the level of information provided by the PME is appropriate. For instance, we are currently conducting an experiment in which we investigate to what extend the PME can be used to evaluate design and usability issues.

The PME's implementation of ACTIVEMATH runs reliably since March 2002. A demo is available under `http://www.activemath.org/demo`. Experiments are being conducted with the different PME versions in order to find out which one is the most appropriate for a particular purpose and type of user and which is least distracting.

Acknowledgment We thank Michael Dietrich for his work for the implementation of various PM eyetrackers in ACTIVEMATH.

Abstract: This paper will report on a work in progress. The research investigated senior health sciences students' perceptions of their experiences in a problem based learning (PBL) class conducted exclusively online. Nurses, midwives and graduate neonatal nurses with previous experiences in face-to-face PBL participated. Qualitative data were collected using reflections, focus groups, and interviews, which focused on participant's perceptions of the PBL process and learning in the online environment. The PBL case and resources, as well as the design of the conferences will be briefly introduced. The focus of the paper will be on the preliminary findings of students' perceptions about group process and learning in the online environment. Limitations of the research and implications for future applications of online PBL will also be addressed.

Introduction and Study Description

Little is known about conducting PBL exclusively online. This paper reports on senior health sciences students' perceptions of their experiences in a problem based learning (PBL) class conducted exclusively online. Students with previous experiences in face to face PBL self-selected to participate in the study. The three student subgroups included 7 third year undergraduate nursing students, 5 masters students in neonatal nursing, and 10 fourth year midwifery students. The three tutors were all experienced in PBL, but were novices to teaching and learning in the online environment. All students knew each other from prior face-to-face meetings and all but one student were new to online learning. The groups communicated exclusively using First Class computer-mediated communication software and participated primarily in an asynchronous mode. All groups also used chats to communicate; generally the chats happened weekly. A digital case related to fetal alcohol spectrum disorder (FASD) was developed for all groups to use as the trigger for small group learning. The case included videos, web resources, relevant documents, and case records. In addition, content experts and a legal guardian, who cares for children with FASD, were trained to communicate asynchronously with students online. The PBL experience lasted between 4 and 6 weeks and students were graded on their participation.

Qualitative data were collected using reflections, focus groups, and interviews. The questions for the reflections were modified from Stephen Brookfield's (1995) work and were completed weekly, where possible, by students throughout the online PBL intervention. At the end of the intervention, focus groups were conducted with each class; interviews were held with students who could not attend the focus group. Focus group and interview questions were focused on the PBL process and learning. For example, in what way was your online PBL experience different from your past face-to-face PBL experiences? Can you comment of the nature of your discussion in your online PBL experience compared to your past face-to-face PBL experiences? What did you like the best/ least about participating in a PBL online? The interviews and focus groups were taped, transcribed and modified after checking for errors. N-Vivo qualitative analysis software was used for analysis. Four members of the research team independently coded one focus group transcript and met to discuss similarities and differences in coding. Using consensus, a master code list was developed and applied to all the data. New codes which emerged were also discussed with researchers. All of the data were chunked into meaningful segments and first level codes were assigned. Currently, the codes continue to be arranged into pattern codes, which hold commonalities and form sub-themes. This paper represents a work in progress and reports preliminary findings of students' perceptions about group process and learning in the online environment.

Preliminary Findings

Issues

A number of problems were experienced by participants in their online PBL experience. Group decision-making was time -consuming and challenging in the asynchronous environment due to the lag time in reading and writing asynchronous postings. Chat (real -time discussion), which was a feature available but not required to be used by the group, was valued by the three groups as a strategy to overcome the problem … "I thought [chat] was a good way of bringing everybody together and providing some direction for the rest of the week in terms of what we were doing." Another student felt that "For me the chats at first they were overwhelming, but it was the only time when the group would make group decisions, and you wouldn't take a week after to decide where are we going now."

For some, the PBL online experience felt overwhelming. This was largely related to workload, which was perceived to be heavy for reading and creating notes. A sense of cognitive overload was evident which was due to multiple discussions taking place at the same time in asynchronous discussions and real-time chat. In chat, nurses felt that "it just seems so chaotic. It's like we're in a room and everyone is talking at the same time and not waiting for someone to answer, and then they'd answer later. To me it didn't work with my brain. Like, I couldn't follow it." Cognitive overload was also experienced in asynchronous communication when notes related to multiple subjects were all posted in one folder. The creation of specific folders for different topics eased this problem. "Having separate folders for me makes it not feel as overwhelming as the first layer did with only one folder for all objectives."

Most felt that online PBL took more time than face-to-face. As noted by one nurse, "this is so time-consuming!! Reading and responding to everyone takes 10 X the amount of time online than face to face." Brainstorming issues also took longer online. A midwife wrote "It took SO long! In person, we can usually brainstorm and set objectives in half an hour." Students felt an ongoing need to be frequently online. One nurse felt "perpetually guilty about not logging on enough, not posting enough e-mails, and not responding to enough postings. It was beginning to consume me and I was not happy." A midwife felt the need to log-in daily. "It really felt it was hanging over your head all the time. . .But oh,. . . you haven't been on there. You are going to miss out on all of the good stuff. The feeling was "Oh I have to get on there."

Another problem was the need to be sensitive in the creation of notes and the potential for misinterpretation of notes due to a lack of non-verbal communication. One student wrote that". . . it has been a challenge to phrase and write things, so as not to accidentally offend anyone." Information that was presented was repetitive at times and students felt a sense of pressure to show their knowledge. A midwife felt that "I find it frustrating when people post info that has already been touched upon or presented… It's almost like people think that they just need to get something down that can be graded… but it just makes it redundant and boring." This also illustrates the influence of grading on individual participation. Grading was viewed as a motivator, made students accountable, increased the time students spent online, created more stress, and influenced students to increase the amount of content they presented. Some students felt that "it would have been easy to let it slide" if PBL was not graded.

Advantages

Despite the problems, a number of important advantages were identified. Students had more time to reflect, process and analyze information through the reading and writing process. Students noted that they refined their online contributions from "barfing information on the screen" to "[focusing] research into key areas . . .[and presenting them] in a succinct way." One midwife commented that, "something I really liked about [First Class] was the depth of information that was posted. . . . It's like the academic work is actually done." A nurse felt that "you really had to synthesize it because you were putting it down on paper and words." Another felt that, "resources had to be more critically analysed, [as well as] what was posted for the content that it had, versus just coming to class and bringing something." A midwife felt that, "when we're in person we tend to go off on more tangents. . .[in]online learning, we stayed a little bit more focused, even though [our tutor] did give us the feedback – ok we need more analysis of information, not just information, but analysis of it like looking at the studies."

More time and place flexibility was another advantage of online PBL as indicated by the following comments. "I am enjoying doing it from the comfort of my own home" and, "I really liked that I could go in and do it any time because that was convenient having kids at home. I could go in when they're asleep. . ." One neonatal graduate nurse gained a new appreciation of the use of the chat feature to connect with people from a distance. She explained ". . . I was on holidays so I hadn't talked to anybody for a whole week, and then I came to the chat that night. It was like, oh, there is everybody. This is great! So maybe if you were in a distant setting and that was the only time that you came together that you might have a different view of [chat]."

Opportunity to learn at one's pace and flexibility to learn in a style that suits one's individual needs was valued by many participants. A nurse indicated that "I know it's neat to have so much available, because usually the tutor has all the information and you have to draw it out. But this way, like according to your style, or how much you wanted to know, you could just access information." Quiet group members felt able to participate more and be heard. One nurse stated, ". . . I'm usually a quieter person, but it's easier for me to sit and think about things and then post them rather than if I'm face-to-face . . . the group keeps on going... So yeah it's like doing it on your own time." In addition, peers could hear more from the quieter members and gained an appreciation of their peers' depth of thought compared to their face-to-face PBL experience.

> "I think what I really liked about the PBL online ... was that the people whose voices I don't often get to hear [in face to face classes], I did [hear] in the [online] PBL. . . The appreciation of the depth that people were at, that I don't always get to hear in class. And, I feel like sometimes that that's the downside of the PBL format. From an oral perspective, is the sort of the more outgoing or vocal or people who articulate more comfortably . . . They tend to speak whereas [with] someone on the computer, your voice is always the same.

This quote also supports the finding that there was a sense of equality among group members. A nurse explained, that "everyone was more equal, because in our group setting there [are] always more quiet members. But there were no quiet members, because everyone had to put their postings on. So, it was very equal in some respects."

Many students felt that they learned online from peers. For example, a midwife explained, "I was very proud I actually could find the SOG Website, but that's because CS's been using it. So I think what's been happening is more of a filter thing that within the class we have LD, the computer maniac, and here's filtering down to other people. And it's kind of just a little bit of a trickle thing that I'm starting to pick up." Many students also felt that they gained knowledge and skills in computers, Internet web resources, and online etiquette. One midwife stated that, "I really needed to learn computers, so this was a really good exercise personally." Another stated that "[Online PBL] has increased my confidence in computers and now I know how to do email by myself." One nurse, felt "most engaged during the research component for this class. I found out some good resources online."

Although students did not have access to simulated patients for their online PBL experience, as they typically would in a face-to-face class, they appreciated the sense of reality they felt in certain aspects of the online PBL experience. Discussions that had applications to real clinical scenarios and contact with "real" people were valued. A midwife felt it was "most engaging when other students talked about real case situations, [which] made [her] think about how to put the theories that [they] talk about into practice." One midwife noted that. ". . . having a real person with real experience [as a resource for the case] was really good, [and the resource person made] all the same spelling mistakes that we were making." Videos also helped some students feel that the case was real. They valued the modeling of the interviewer in the videos of the case scenarios.

Most students struggled to understand what was considered successful online participation. "I am still not clear [about] what the expectations are of us... I get the impression that people are trying to independently answer every objective. I was more under the impression that we are to build on what's already there." Students wanted clear expectations and feedback from both tutors and their peers. One nurse felt "[my peer] put things (group issues) into perspective and calmed my anxieties. It felt good that she acknowledged my position and reassured me that I was not alone in it. As well, today when I received [my tutor's] e-mail I felt TOTALLY affirmed. Not only did [the tutor] agree with some of the points I had raised, but also gave us guidance, suggestions and affirmation that we were ALL doing a great job."

Summary and Next Steps

Our findings are transferable to contexts which are similar to those described in this study: students and tutors new to online learning and experienced in PBL. The short time that they spent online and the high learning curve that they experienced undoubtedly influenced their perceptions. The fact that students were not true distance learners (they continued to see each other in face-to-face classes) also likely affected their communication online and their perceptions. Finally, there may have been some bias introduced if students told the researchers what they thought we wanted to hear. However, students appeared to be open to sharing their perceptions of their experiences. Future analysis of the data will include the data from online chats and posted notes to further inform us. Their ongoing reflections may identify changes in feelings over time and will also be investigated in future analysis. Although it is too soon to make recommendations from our findings, strategies to overcome the problems identified in this study require attention by online educators. On the other hand, benefits of online PBL can be supportive for health sciences students learning at a distance, as well as in hybrid (mixed face-to face and online) courses.

How To Debit Their Scores?
An ICT Solution To Assess Accountancy Students.

Dirk Vanderbist & Jan Vanthienen
K.U.Leuven, LIRIS, Department of Applied Economics, Belgium
{dirk.vanderbist,jan.vanthienen}@econ.kuleuven.ac.be

Abstract: The introduction in 2001 of a centralized E-learning platform at K.U.Leuven brought challenging opportunities for accounting courses to engage in E-learning. This paper deals with the problems encountered in the development of electronic tests and remediation exercises. First a list of requirements, to make the exercises as realistic as possible, is presented. Then we give an overview of issues with the available ICT platform and we end with a discussion of the newly developed software.

Introduction

In 2001 K.U.Leuven chose a centralized approach (Toledo 2002) for implementing ICT to support courses and learning activities in one learning platform based on two commercial products. For electronic courses K.U.Leuven opted for BlackBoard and for electronic test and remediation exercises Question Mark Perception[1] (QM 2002) was implemented. For most of the courses at the Faculty of Economic and Applied Economic Sciences, going from paper to other media only caused minor problems. Making electronic versions of accounting exercises related to accounting courses is a lot trickier and the focus of this paper is to elaborate on how electronic test and remediation exercises were implemented (GIZEH 2002). The main problem to tackle has been the typical tabular format for accounting. Not finding any satisfying commercial product resulted in building an interface between QM and a newly developed tool. The goal was to enable students to do their tests and exercises in the same flexible way as they would be doing them on paper. The reason ICT was preferred to paper boils down to time management. Using ICT for these tests and exercises allows providing students with fast evaluation and feedback because it is generated electronically. Tutors can now focus on providing support to students really needing it without loosing time with batch correction jobs.

Requirements

First of all the exercise's representation should look as natural as possible. This limits the possibilities of multiple-choice questions to assessing the theoretic parts of the course. For exercises a representation close to the T-like scronto format or the tabular journal format is needed as these are the two formats allowed according to the Belgian's accounting standards. Another requirement was that the tool should be very flexible when dealing with inaccuracies of the student. This was realized by providing ranges for account numbers and ranges for amounts. The ranges of account numbers were to overcome the situation were one or more account number in a group is considered correct. To bypass rounding errors during calculation the ranges for amounts were provided.

Finally specific requirements to aim at for scoring questions and providing feedback were outlined. The answers will be evaluated based on two factors both worth half the exercise's score. The first part considers the correct structure, meaning the correct account numbers and corresponding account descriptions, which is either correct or incorrect resulting in null or the full marks. If the structure is correct the second part is evaluated were the accounts' amounts are looked at. Every correct account is worth the same and the score is expressed as percentage to the maximum given by the correct answer making up the score for the second part. The feedback is adapted according to the student's answer. If the student returned a blank answer he will only receive a hint indicating where in the course the answer can be found what discourages students trying to collect exercises.

---

[1] the version of QM referenced to in this paper is 2.5.0.0

When the structure was answered incorrect the student receives the correct structure as feedback and the feedback for mistakes against the accounts' amounts is the correct answer to the exercise. Every feedback should also provide a unique reference label. This label enables students to refer to specific exercises during communications with their tutors.

Challenges & Solutions

In general we found out that accounting exercises do not fit well in the features provided by E-learning ICT tools because of the lack of flexibility needed as indicated in the requirements. Initially we tried to use basic question types available in every ICT product. While multiple-choice question could be used in theoretical questions they were ruled out very quickly as accounting has nothing to do with selecting the correct answer. A second attempt was made with fill-in-the-blanks questions. Here we were able to get very close to the requirements but some semantic and syntactical problems also ruled this out in the end. Other question types were not considered useful.

Because its used principally in exercises, the tabular journal format was implemented (Figure 3). It represents the different participating accounts in one accounting transaction. In the first column the account numbers and account descriptions are shown grouped together around the ones that are debited, before the '@'-symbol, and the ones that are credited. In the following columns the amounts by which the corresponding accounts are debited, first column, or are credited, second column, are indicated. The first property laid down was the size of the table. It should allow the students to answer most, if not all, types of questions. We opted for one fixed format with four debit accounts and four credit accounts. Providing exactly as much rows as needed would give away the answer as students will start recognizing answer patterns and providing the number of row in a dynamic way has very high load times and evaluation response time because of the dynamic structure's size and complexity. The solution with the fixed table size overcomes both problems and is still very flexible. The students are allowed to enter their solution in any order, as long they respect the debit and the credit groups, irrespective of the position of unused blank space.

The things we could not do flexible enough in QM using its basic features lead to the implementation of an interface with QM. Firstly, we would like to complete the account description when the student enters an account number as every account number has a fixed description. For a student this is valuable feedback. Secondly, we like the required flexibility dealing with the way a student enters his solution. As indicated before the order and the position of accounts and blank unused lines should not play any part. Semantic problems made it impractical to implement using these basic QM features.

The semantic problems have to do with the way exercises are corrected and the way the maximum score is calculated. For correcting exercises a set of logical expressions is used. In QM logical expressions may not contain parentheses to guide the evaluation and consequently have to be serialized to overcome this. However due to combinatory explosion during the serialization process, because of the nature of accounting questions, the expressions surpassed the question size upper limit. A second semantic problem is about the way QM calculates the maximum score of a question based on a set of logical expressions. QM calculates the maximum score by adding all the scores potentially given by every expression in the set together not taking into account that some expressions might be mutually exclusive. It is possible to overcome this by intervening directly in the DB, storing the QM generated exercises, and by adapting the scripts that generate the grading reports. Since this is dependent on the QM version it was not considered an option.

QM is not optimal for representing accounting exercises directly but still used, be it through an interface, and there are some good reasons for this. First of all QM is a standard with K.U.Leuven so support is guaranteed. Second it is better for students to have a limited set of standard tools they have to work with. The last argument is that if we implement an interface with QM it is possible to use its report generator, deployment options and user management without having to implement this ourselves.

Implemented Solution

The relation between QM and the developed software is indicated in Fig. 1. The software basically consists of two parts: an authoring tool, B2QML, used by the tutors to generate the accounting exercises and a Java applet, QMB, used by the students to do their exercises. The software satisfies all the requirements previously indicated.

QM Perception Report Generator

Figure 1: Relationship between QM, B2QML and QMB

B2QML (screenshot in Fig. 2) is capable to export exercises in the QML import format for QM questions. B2QML checks the validity of the question and verifies the question for semantic author mistakes. Generating accounting questions directly in QM with all the evaluation aspects is very complex what makes it error prune and therefore we chose to use an authoring tool instead. Moreover HTML is used in the deployment of questions, QMB applet encrypted parameters have to be set and the logical expression for the evaluation have to be written down which was considered not to be within the typical author's range of skills.

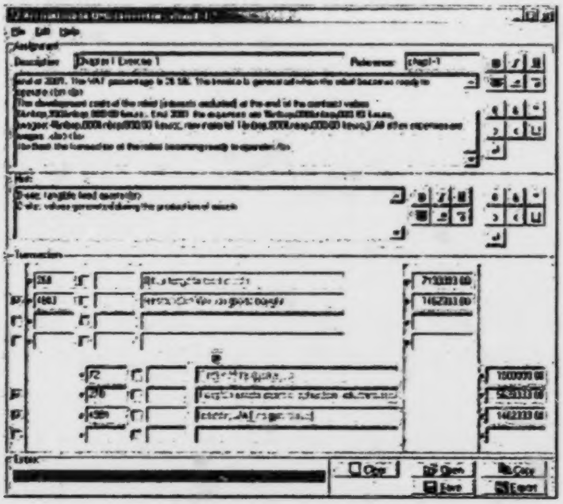

Figure 2: Screenshot B2QML

The student interacts with the QMB applet (screenshot in Fig. 3) that is embedded in a dynamic web page generated by QM. QM passes, through parameter binding, all the necessary information to the applet to enable the applet to evaluate a specific exercise. When the student submits his answer the QMB applet passes the score back to QM and the latter will generates a web page containing the feedback according to the score. Because the answer to the exercise is visible in the source of the generated web page as the parameter list of the QMB applet we apply an encryption algorithm to the parameters. The applet provides the author with an option to reveal some aspects of the answer. These parts are shown as pre-filled content fixed input zones in the QMB applet.

BEST COPY AVAILABLE

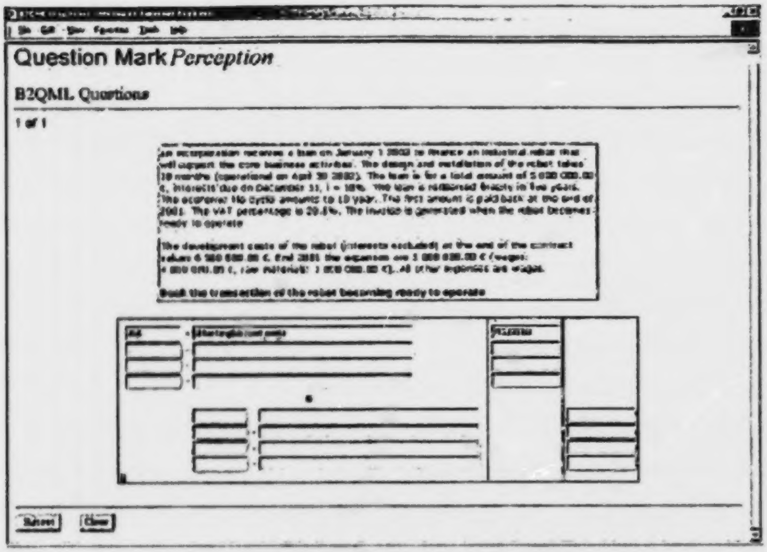

Figure 3: Screenshot QMB (first row fixed)

There are some other advantages to this approach. The QMB applet can be embedded in any web based environment as it is a stand alone piece of software. In the near future it will be used in a CD-Rom based accounting self study package implemented by means of Praktix Presentation Viewer (PPViewer 2002) which is a table based hypermedia viewer developed at K.U.Leuven. The authoring tool, B2QML, is language independent. The whole tool is based on definition tables. Only the translation of these tables is needed to implement a version of the tool in another language what makes the tool very adaptable and allows for easy maintenance.

Future Development

For the moment the solution discussed in this paper only allows accounting exercises represented as one entry transactions in the journal. Viewing them as a series of one-entry transactions and providing a QM question for each of them is the only way to support exercises having more entries. Implementing a real multi-entry exercise would make the exercises even more realistic compared to real live accounting but the trouble is the combinational explosion during evaluation of such exercises. Belgian accounting standards do not provide a fixed order and moreover it allows entries to be combined or uncombined leaving the implementation as a very complex but tempting problem for future development.

An infrastructure of Possibilities: Distance Learning at the University of the Sacred Heart

Antonio Vantaggiato
Distance Learning Institute
Universidad del Sagrado Corazón, Puerto Rico
e-mail: antonio@sagrado.edu

Abstract: This article describes an academically valid and sustainable model for Distance Education that we are building at the University of the Sacred Heart. The philosophical assumptions (hybrid or blended model), the pedagogical tenets (holistic view of Web-based course creation), and the organizational structure of the model are presented. First, the importance of participation of all actors of the academic arena is stressed. Then, after describing the reasons that back our Institution's decision to use the Web as the major support and medium for Distance Education, the case is made that what we call the "infrastructure of possibilities" is a feasible model of co-creation and sharing for Web-based DE. Last, among the requirements of such an infrastructure, the need of suitable tools to use the Web's potential is described, and one such tool, LinksKeeper, is presented, that helps to create a cooperative environment to catalogue and share the Web's resources.

Introduction

Distance Education (DE) at Sacred Heart University is a transformation of possibilities in education, and therefore a highly cultural project. Though objective socioeconomic reasons impel university institutions to adopt distance education (in Puerto Rico, demographic changes, among other factors), the University of the Sacred Heart has decided to create a model of its own to help the institution to fulfill its institutional mission and to serve better its community by producing effective learning on-line strategies (Abraham 98). This article thus presents a model for distance education that is being designed at the University of the Sacred Heart, based on the participation of all the interested actors in the academic environment.

Our model has one basic tenet: it is a work in progress, a skeleton being filled and configured by all the interested parties. We started with only a few guidelines (for instance, we do not want the recreation of textbooks in a different medium (Anderson 97); instead we seek to build whole experiences around each course that use the new medium in novel ways), and let faculty and the other actors invent their own play. This way we argue it is possible (and sustainable) to foster a serious spirit of creativity while enhancing the academic-learning experience.

The Distance Learning Institute

We designed an agency that could foster such an environment and atmosphere, an agency made of faculty for the benefit of faculty. The Distance Learning Institute (InED, for its Spanish acronym) was thus born out of a necessity; its mission: to propose and foster discussion of policies; to research and develop critical applications that may help faculty and students in the new endeavor; and to research pedagogical/economical issues pertaining to distance learning. The Institute's nature is so dual: educational & technological, and in setting so, we established a primary center in Puerto Rico to work in the intersection of the two areas.

Thanks to the Web revolution, we have come to believe that DE represents an opportunity without precedents for a pedagogical-economic revolution that extends and transforms the dialogue between the main actors of the academic environment. At the same time, we think that DE allows to take care of those problems that the social changes of students present us. The Distance Learning Institute was created, therefore, to establish the institutional infrastructure to manage the ambitious objective of creating a better university.

First, to us, on-line education is equivalent to education supported by the Web, without renouncing the current physical component we consider important to maintain and refocus. This way, we do not propose on-line education like an alternative, but like an evolution of the educational paradigm, in order to center the process around the student.

An Infrastructure of Possibilities

Our infrastructure of possibilities has the following goals:

- To extend the dialogue between the actors of the academic community;
- To have information flow promptly and constantly to those who need it at the time they need it;
- To eliminate the classic educational barriers of space-time;
- To help students in the acquisition of the abilities of reading and of critical analysis of new media; so to have them overcome information overload and start producing knowledge;
- To create synergies between vital components of the internal and external university community, beginning with the assumption to use and to develop novel programming, based on open source code and nonproprietary standards (Vijay Kumar 2001) (so that students can be both producers and scholars, creators and analysts); this synergy is strongly centered in Web technologies and human resources and includes the central axes of the University's academic vision: Community Linkage & Service Learning (practice inside and for the community, development of civic sense, understanding of other people's realities), on-line Education, and the project "Language and Culture throughout the curriculum".
- To never stop to think about the project in terms of a great experiment, in which all are observant and observed simultaneously.

This experiment in the infrastructure of possibilities must adopt strategies to make this project a sustainable one. This implies the incorporation of faculty in the project from its earlier phases: we have worked on this by means of the participation of faculty in the productive debate on copyright issues, the very philosophy of DE, and its pedagogical methodologies, so that faculty can creatively evolve in the process of course design in the absolute respect of its freedom and personal creativity.

Why the Web?

Because the Web represents a revolutionary technology with a very simple interface that:

- Permits to extend the dialogue between the actors of the educational process;
- Permits to share experiences and resources, and to cancel geographic barriers: it is global, but simultaneously it emphasizes locality;
- Virtually eliminates the classic constraints of space and time: a course becomes a complete experience, even outside the class schedule and the campus;
- Ease the use of effective pedagogies based on the student as the center of the education-learning process, such as learning-by-doing, cooperative work and the linkage of studies with the necessities of the community;
- Permits the reusability, in different contexts, of didactic and nondidactic materials available around the world; this concept expands through the emerging Learning Objects standards (Wiley 2000).

The aspects mentioned above legitimize our belief that it is feasible to take advantage of the synergy that can be obtained by integrating several resources like original materials of the professor, programs and resources, articles, multimedia material and other on-line courses, all available through the Internet. We believe that this way it is possible to create more than courses, holistic on-line experiences, in touch with the world, of high quality and relatively low cost. We emphasized that we do not want a text book re-creation (Anderson 97): being it a new medium, we must give ourselves the opportunity to understand and assimilate the crucial aspects of this new technology. Only thus (that is to say, when we master the technique) will we manage to be truly creative in the production of on-line courses. We want to develop faculty able to create independently, and to master therefore the cybernetic techniques like pencil and paper.

Our model is academically valid: it encompasses three phases over one summer and two semesters: course design and creation, first methodological revision (while the course is being offered), and one second revision of contents, in order to adjust the course to the necessities and points of view of all the professors who deliver it. It is also economically sustainable since the courses' cost of development, although high initially, tends to lower when the potential of the new pedagogy centered in the student will reach maturity and be a compelling factor for faculty. Also, we think that in the mid term, the adopted approach allows professors a better control on courses and therefore a better quality of life: perhaps less time as "sage on the stage" and more in fruitful and vital discussions; time to dedicate to research or the didactic creation process. Also, the InED has plans to consolidate its activities including publishing learning objects and modules, and act like a brokerage agency between the market and the faculty interested in authoring these objects. This plan, if it is demonstrated viable, could considerably reduce the costs of future development of on-line courses.

Of course our model of an infrastructure of possibilities must develop and provide a strategy and the means so that faculty may express its creativity and maintain its academic freedom with the conscious and creative use of Web technology. The strategy to achieve this encompasses the following issues:

- Opportunities for on-line discussion and work must be constructed;
- Faculty and students are given the opportunity to learn, understand and use this technology;
- An effective capability to use the computing and Web resources in daily educational and non-educational activities is provided to faculty and students;
- Ample participation is given to faculty in all the essential questions that concern it, like distance education policies and authors' rights issues, among others; and
- Suitable tools are provided to faculty to take advantage of the Web.

LinksKeeper

The Internet was built around the idea of redundancy of paths. Nor content and its accuracy and usefulness, nor the fact that this content would eventually overwhelm the people who needed it the most was at stake (Etzioni 96). Only after the WWW was created, the inherent problems of content usage and usefulness emerged as main issues. In fact, the Web was born out of the scientific community's need to share content. However, the Web's infrastructure and protocols were not designed with these issues in mind, so we still see problems with respect to:

- Content usefulness and accuracy, and
- Information overload.

Since the Internet is all about links and sharing, we addressed these issues with a mechanism to build and share collections of useful resources out of a collaborative effort. So we designed a tool that people of a given community may use to add and catalogue their own Web resources: resources that each of them finds useful in a given context, class, research, or personal use. These common resources would be assured to be of generally high quality since they are catalogued by the very same users. We wanted also the catalogue to be annotated, because only from the annotation metadata would other people understand the usefulness of a given resource.

We implemented LinksKeeper, a cooperative client-server tool that provides users with a drag and drop interface to catalogue resources (manually) (Keller 97), (Li 99): users drag the resource they want to add (from a browser) over the catalogue item they believe the resource must be in, and drop it there. Last, they annotate it with their own considerations and comments. On the other hand, users who are in need of some specific resource will do the inverse operation, and will have no trouble in finding what they need, since the catalogue is annotated. LK is developed in Java, while the server part is developed using open source standard software such as mySQL. This application is thus fully portable across platforms, and is freely downloadable from the Internet (users need to subscribe explicitly.)

Our intention is to extend and improve the program to incorporate the creation and the storage of repositories of learning objects, using the available standards of metadata. Also, we are improving the program to discover nonfunctional links automatically and to solve the problem of how to replace them with others. Also we want to tie LinksKeeper to a Pan-Caribbean Repository of educational resources, particularly in areas of interest for the countries of the region.

Organization

It would not make much sense to have such ambitious plans without a strong organizational structure for the Institute. We believe we have achieved such a structure by:

1. Directing the Institute's work through shared responsibilities among three top positions that merge engineering, computing and pedagogy with political and communications expertise;
2. Integrating students within the day by day life of the Institute.

Students thus manage, research and develop software and Web content (a portal, various websites); they also manage our networking infrastructure. Through synergy among the Computer Science, Communications programs, the Laboratory of Artificial Intelligence and the Service Learning effort, we believe we can both use the talent of our students to produce interesting work, and transform them into co-managers and scholars. The forthcoming Master's Program in Informatics (oriented towards Internet technologies) will also help the Institute to be a practice field for all its students.

Of course, no major institution-wide project works without some hindrance or friction, especially when new units are created. Thus, management plans have to deal not only with project "evangelization" among faculty and administration, but effective action must be taken with academic and non-academic units. Thus, the highest-level commitment is of utmost importance: a paladin for the project needs to be there at all times. At the University of the Sacred Heart, our President supports wholeheartedly both this effort and the Institute.

A Generic Platform for Presenting Learning Material:
Praktix Presentation Viewer.

Jan Vanthienen & Dirk Vanderbist
K.U.Leuven, LIRIS, Department of Applied Economics, Belgium
{jan.vanthienen, dirk.vanderbist}@econ.kuleuven.ac.be

Abstract: When developing courseware it is important to separate the learning material's content, the navigation through the content, and the content's layout in order to enable maintainability. Praktix Presentation Viewer is a generic platform to deploy course material based on this separation between content, navigation and layout. This paper discusses the concepts, features and techniques behind the generic platform.

Introduction

When the Faculty of Economics and Applied Economics at K.U.Leuven wanted to provide self-study course material on CD-Rom the option was taken to separate the learning material's content, the navigation through the content and content's layout. From the beginning it was clear that it should be possible to maintain the course material without having to use any courseware specific tools as this would make maintenance more difficult and vendor dependent. It should be possible to add, edit, delete or reorder learning material with common available tools. There have been too many examples of nice courseware lost, due to the impossibility maintaining it: hard coded navigation, vendor locked-in material, etc. A first generic platform, called Praktix, was built in IconAuthor, and was used to present course material on end user computing software. In order to apply more standard components and to increase flexibility the platform was rebuilt in Borland Delphi and renamed Praktix Presentation Viewer (PPViewer 2002). Meanwhile, the generic platform is being used successfully to deploy electronic learning material for other courses of the faculty's Information Systems Group.

Requirements

First of all some general requirements were outlined linking the platform's concepts to the E-learning principles: "learning just in time, learning just for me, learning just enough". Most of the concepts have been implemented since the first version of Praktix.

It was stated that the implementation should aspire to:

- *reusability*: decoupling the learning material's layout from the learning material's content
- *ease of maintenance*: decoupling the navigation from the presented content
- *integration*: trying to stay as much as possible within the boundaries of the platform
- *extendibility*: supporting the possibility to extend the platform for special needs
- *ease of deployment*: deploying the platform should mean no, or few very special, software components that have to be installed on the user's system
- *guaranteed continuity*: if the platform's development stops it must always be possible to recuperate the learning material's content
- *enabling independence*: for the main functionality no network connection should be needed

These requirements lead to an implementation dichotomy between the generic platform on the one side and presentations on the other side. By a presentation we mean the whole of learning material brought together for one course to be deployed electronically.

Distributing learning material for courses simply means putting the generic platform and one or more presentations on a CD-Rom. A CD-Rom is used as medium because it allows storing vast amounts of multimedia information relatively cheap. Bandwidths of networks are still a constraint as they are insufficient to support the same multimedia as streaming information at every moment of the day. If this bandwidth constraint would be lifted the implemented platform is equipped to embed streaming media and as such ready to follow this new track. In the early versions the focus was on making the presentations as network independent as possible since network connections for students were not obvious. This constraint is becoming less strict as discussed in the paragraph about future development.

Concepts & Features

In this paragraph we will discuss the features and techniques used in the learning platform according to the parts indicated in Fig. 1.

Figure 1: Praktix Presentation Viewer features

Hierarchical Topic Database

The topics of a presentation, presented as a hierarchical tree structure that can be expanded and collapsed, is loaded from a topic database into the topic tree as shown in Fig. 1. Every presentation has its own topic database. This topic database contains for every topic an indication of the position in the topic tree which is also used as unique topic identifier for navigation between topics. Furthermore it contains the topic title as shown in the tree

BEST COPY AVAILABLE

structure and a link to the file holding the topic's content. It is this file's content which is shown in the topic content part when the user navigates to the topic. When no link to a file is provided the application generates and shows an index table, in the content part, of the topics one level down in the topic tree. The last entries in the topic database for a topic are links to external applications, called external objects, and links to other topics, called internal objects. For performance reasons, the database is momentarily implemented as a flat text file and loaded once into the tree structure when the user opens the presentation.

History

The topic tree keeps track of the items the user visited by changing the colour of the topic titles of the visited topics in the topic tree. This history enables the user to identify the topics he already studied and the ones he still has to acquire. The history is one of the few things Praktix Presentation Viewer saves locally to a file on the hard disk but only if the user wants to save it. The other things saved locally are the default presentation to open on start up if a CD-Rom would contain more presentations and some version information that will be discussed in the paragraph dealing with future development.

Topic Contents

The topic contents are in fact web pages. We opted for the use of web pages because of the ease with which objects can be integrated: text, slideshows, figures, spreadsheets, databases, connection to other testing and learning platforms and other multimedia material. We integrate web pages at basic HTML level. The advantage of this is that it limits the required knowledge of the presentation's author as most office suits nowadays allow exporting files to HTML format. The disadvantage is that HTML can easily be used incorrectly by ignoring the advantages of XML or CSS and by hard coding file paths, ... The latest is really important. Direct links to files should not be used because of the maintenance problems. The generic platform provides an alternative by allowing references to the unique topic identifier in the topic database and providing a topic for the direct link to a file. Objects that cannot be integrated in a web page can always be provided as link to an external object.

Links to Related Topics – Internal Objects

Links to related topics act as 'also take a look at'-pointers for students by making relations between different parts of the course. They are implemented by adding the unique topic identifier to the list of related topics in the topic's entry in the topic database. The user can navigate to those related topics by just clicking on a topic in the list as shown in Fig. 1.

Links to External Application – External Objects

Objects that cannot be integrated directly in a topic's content web page can be provided by means of a link to an external object. The topic database contains a parameter list that is passed to a helper application to open the object. Examples are IBM ScreenCam movies, MS Windows help files, MS Office Wizards.

Navigation Shortcuts

The navigation shortcuts correspond to the typical web browser navigation buttons and to some navigation buttons specifically designed to enhance the topic tree navigation. Two important navigation buttons to on-line web pages were added: one to a list of errata and one to the course's website. The latest allows easy integration with other volatile course information, such as course schedules, and course related material, as presentations and papers, which would be outdated very fast when placed on CD-Rom.

Skins

Since the platform is generic this could easily lead to a high degree of sameness of the presentations because of the shared generic GUI. To overcome this the possibility to use skins was implemented. The skins allow the author of a presentation to customize colours, background images, button icons, navigation icons, titles, … In Fig. 2 a filled and an empty skin are put next to each other to show the power of this option. These skins allow authors to make something reusable, based on the content, but still unique and capable to stand out among other presentations.

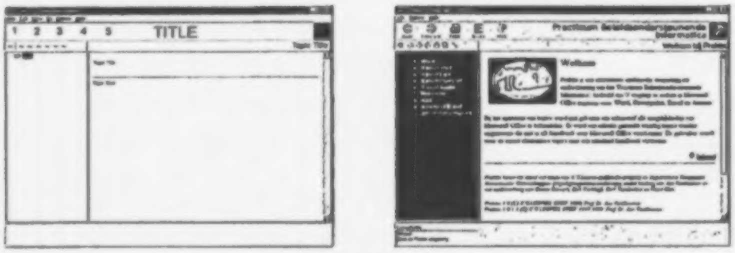

Figure 2: empty skin (left) and filled skin (right)

Implementation

For the moment two implementations make use of the Praktix Presentation Viewer. One is Praktix, the end user computing software self-study package where Praktix Presentation Viewer finds it origin. The other is a self-study package about SQL exercises. The way the presentations are organised on the CD-ROM allows them to be easily shared with other course authors by means of knowledge pools.

Future Development

For the moment Praktix Presentation Viewer is a MS Windows application. It works fine on every version of Windows: 95, 98, NT, 2000 and XP. For Windows 95 some update packages need to be installed first. To enforce this we only have to give up some minor features. We opted for the broadest compatibility possible since not all students have access to up to date and high-end computers. In the near future we hope to add Linux to the supported platforms. Since the software development environment we used also runs on Linux we expect that only minor modifications will be needed to realise this.

Furthermore we would like to add some kind of automatic upgrade facility. When the user starts the Praktix Presentation Viewer from CD-Rom it will check whether a newer version is available to download or a newer version is installed on the user's computer. If a newer version is installed this version will be used instead of the read only version on CD-Rom. If a newer version is available to download it will be installed on the user's computer replacing any outdated version. In either case the user will always be equipped with the latest version.

In the long term we are hoping to port the application to a web based application in combination with a web server that holds the presentation's content. It also solves the problem of having to store the history locally on the users' hard disk as it would be stored on the server. For the multimedia information we hope to provide everything by means of a streaming media server.

Abstract: This paper examines influences resulting in changes in managerial training and development with particular reference to the University of Guadalajara, Mexico. It starts by examining conditions at the macro and micro levels that bring about change, the nature of change, and the present and future education and training implications to increasing demands on management within diverse organizational environments that are becoming more complex and uncertain. Technology is playing an increasing role in management education and training. Through the use of open and distance education technology learners have greater flexibility of time and place of learning. In addition, where transdisciplinary approaches are used it is leading to the development of "new types of managers" with abilities, behaviors and values that better enable them to cope. Examples draw on management training institutes in Mexico.

Introduction

A sign of the current times is the continuous change, which is modifying everything. This constant change drags the transition of modern organizations toward the manifestations of posmodernity, which are expressed in individual behaviors integrated by means of technological processes in the same structures. Two new variables enter in scene to define the posmodernity of organizations: their complexity and uncertainty of environments in which they are immersed.

The pace of this dramatic organizational change accelerates exponentially every time. It leaves as a a consequence an enormous human insecurity in the face of structural rigidity of economic, social, political and cultural institutions. These institutions are unable to absorb uncertainty derived from changes, hinder instead of facilitating adaptability of people and also hinder the use of benefits. These benefits can be derived from the great wave of technological revolution of information, which has become a self-transforming movement and transformer of development opportunities and human progress. Although these opportunities are increased it is also evident the increase of threatening phenomena which deepen the feelings of human fragility and insecurity. These propitiate the uncertainty that encourages the traps and dangers of mankind survival.

In this diagram it is summarized some ways in which the future can be visualized:

MACRO	MICRO	FUTURE IMPLICATIONS
Changes in the global environment of the business community are the result of:	Impact on individual managers which leads to:	Alternative approaches to managers:

Productivity improvement of business.	Overload of information Demand for a greater continued absorption of knowledge	Local continued education/ Formal/informal distance learning
Globalization of business relations	Time compression	More concentration on personal development
Economic and technological Changes	Fast changes of leadership and organizational fluid styles	Changes in careers Early retirements
Turbulence	Change requirements for administrative staff.	Reduced activity / without movement.
	Bigger and earlier responsibilities	

The manager of the future, the future of management

The problem of that, as much the individuals as the organizations take advantage of the opportunities that provide this pace of accelerated change, it is reduced to its control and handling. It finds its foundation in the premise of planning changes, as the theoretical sustenance of organization development that aspire to the transition toward the new times marked by posmodernity. Organizational transitions respond to the current expressions of tendencies toward the globalization and internationalization of the markets. These trends have appropriated the advances that the technological-computer science revolution provides. Meanwhile, society is more active, more participating and more demanding of better conditions. There are nowadays, bigger demands for human development and quality of life, greater social justice, formation of cultures that respect diversities, propitiate its solidarity and recognize the human rights.

Professional development in management takes into consideration not only, the emphasis of traditional curricula oriented toward assimilation of knowledge in administrative technology, but also development of the abilities, skills and required competencies for instrumental implementation of changes. But above all, a professional manager development that responds efficiently with attitudes and values as a foundation of practices to face the challenges demanded and required by derived situations of an environment characterized as complex and uncertain.

Instead of developing their work –doing it better, to end up being more experts and able – the managers will have to be achievers. They will be able to look for and to command resources, to determine strategies and to break limitations for implementing them. Instead of concentrating on the consistent use of management systems, company policies and rules, and to focus on high standards, they become operative: operators with a group of values, principles and models, but operators in spite of everything, motivated by will and ability to achieve.

Is it reasonable to ask, "to achieve what"? But the answer to this rests in the future; this future that, without a doubt, will it include the means to make better use of any available resource for us, to improve the quality of life, and therefore our growth and development. The manager of the future clearly has to be, like it was said previously, a good operator, a motivated person that can obtain and to control class resources to achieve results, a highly developed administrator and highly self-confident.

This person can be among the graduate of high ranks at universities. Until universities again can teach an action theory, it cannot be found this developed human being, in such a way that it has to be developed. In other words, the development of managers will become, much more than a necessity of survival as it is now.

To speak of manager development implies a change in education, in such a way that this is the result of experiences, not training of the memory. Education will be a creative-innovative process, (that some futurologists identify as the characteristic feature of a new phase of the technological revolution that we live in our days) in which the manager is able to develop trust, ideas, communication and interaction.

The Japanese Companies take to practice the following process, according to Raymond (1988):

1) What have learned and toward where it can take this knowledge.

2) How the previous knowledge could be incorporate and to be applied to the mark of a new position.

3) How it can improve a new situation when continuing ahead.

This process should also be incorporated to our organizations, because with it not only is learning continuously, but rather also it is a process of thinking and increasing the knowledge foundations, all the time, as well as applying new knowledge to the same one, and advancing toward the leadership. The above-mentioned helps us to manifest that the education should exist for the reality and for the future.

From an organizational point of view it is necessary to have, a bigger demand of administrators who will be able to cooperate, and therefore, with abilities of leadership. From the individual point of view, the manager will have more up to date knowledge.

As it was previously signaled, it is evident the existence of unavoidable revolution in managerial practices that have global impacts and that modify all the organizational variables: behaviors, structures and technologies. The current generation of professional managers has been called to be educated in the "keyboards".

One of the many ways to increase the wealth of those administrative practices, are the learning outlines at distance which have been developing some universities and other institutions until the level where the abilities and competencies of management can be self-taught. With the use of special text materials, exercises, videotaped examples, use of electronic mail and platforms, the learning responsibility can be broadly transferred. Experiments have shown that the tutor's contact can be designated successfully outside of the programs and that the assignments of tasks can be determined in such a way that a self-assessment and self-evaluation is possible.

With implementation of telematics, education was adapted to the constant change operating in organizations, giving place in this way, that education process does not center around the previously established relationships between the teacher and the student. Thus, more emphasis is given to the link between the information that receives the student and the same student. In this form, the learning process is redefined.

Lack of personal interaction can be a deficiency, but at the same time can be replaced by more modern techniques of interactive video. This allows the student to interact in managerial events on the screen and then to ask, to explore, to answer and to make decisions watching the results of his conclusions displayed in front of him. This is similar to a flight simulator where the training pilots can prove their flight skills without risking. The manager can prove different methods in any kind of problem without being exposed, in a short period of time and space.

With distance learning education, transfer of control of teaching-learning process is given to the individual; this decides what he/she needs to know and then he/she makes the best use in the available learning resources for him.

When being developed continuous education technology it is impelled more and more and designed by the individual adapting it to his own desires and necessities, motivating this way his self-development. Some approaches of this self-development are beginning to emerge. These novel education developments at distance are operated on global bases. Education institutions at distance learning will win, when having an audience in the entire world, but they will have to continue being linked with this audience of foreign countries, by means of consultants.

Of course, one in the best ways of learning at the present time, is doing it. A little less drastic are the outlines of active learning, where the executives either manage special projects inside their own areas or in any other part as a planned process of performance. These outlines that have been with us for several years, also have the advantage of the project's value and the test of managers' audacity. These projects can involve individual action or to lead to a team project, usually of a multidisciplinary nature.

In the past, the time taken to obtain experience and maturity has made to management a field of older men whose energy and forces of creativity weakening are inevitably. One only has to look back, to see that the young men have been able to create when an opportunity has arrived to people of great talent. The executive professional youths, with an urban culture, trained in private universities, also well-known as the " yuppies ", they are those that more quickly are assimilating the technological advances and incorporating them to the directive and managerial practices of the organizations.

To be in agreement with the current changes, organizations not only should incorporate to technology but rather the individuals will have a change in mentality as a change in organizational relationships and it will be a change in the managerial style. The incorporation of technology to the directive and managerial practices and the use of the telematic, make possible that organizations structure their administrative outlines in agreement with the necessities and socioeconomic conditions of the country. With this practice, it should improve the competitive position to the international level. The above-mentioned has given as a result the linking of the administrating and managerial professionals with the productive and social sectors.

Conclusion

Concluding, the managers of the future will have to be agents of development of those organizations to which they are integrated. They will be creative and innovative leaders with clear conciousssnes and awareness of their social responsibility, with a strong discipline of work, with a high level academic development, and that they know how to appreciate cultural and social values of diverse countries.

Abstract: The paper describes functionality and implementation of virtual laboratory for electronic measurement and testing based on access to real hardware instrumentation through Java developed interface. Basic principles and structure of developed software are discussed. An applet, controlling an electro-motor, is considered as an example of developed Java interface to the Lucas-Neulle Company experimentation hardware. The approach gives an opportunity easy to set necessary parameters for controlling hardware instruments, easy to perform parameters changing and to obtain graphical result from the real experiment – all through simple Web browser.

Introduction

In every engineering and technicians education experimental work is an important component for obtaining practical skills from the trainee. In many cases complexity and cost of instrumentation are obstacles to quality of training provided to the learners. The Unitr@in is a Lucas-Nuelle Company hardware device, which provides a number of virtual instruments to enable measurement and control of different electronic devices and schematics. It is composed of main module, connected to the computer and additional plug-in modules (Fig. 1) thus permitting different experiments to be organized with the same hardware device.

The main Unitr@in module provides: digital input and output, analog input and output, relays, standard 96-pin connector for plug-in modules, power indicator, high current power supply (used by the three-phase generator), low current power supply and RS232 standard connector. By virtual software instruments one can set amplitude, range, frequency and type of the signals necessary for each experiment.

Experimental work with this hardware needs guidance for giving appropriate sequences and parameters, which control the virtual instruments for each different experiment. The idea is to ensure opportunity to the learners easy to set necessary parameters for the hardware instruments, easy to perform parameters changing and to obtain graphical result from the experiment.

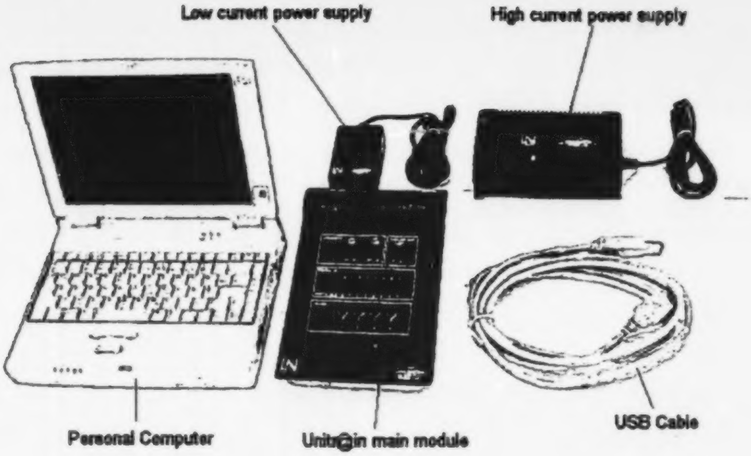

Figure 1: Unitr@in hardware

To fulfil these goals a Java-based interface to Unitr@in instruments has been developed. It permits control of Unitr@in hardware from Java applications and applets. This approach has several advantages. It permits simplified update of the training materials. Number of applets controlling hardware for each exercise can be developed. They are stored on a web server and are accessible for every student to download from the appropriate web site.

Experiments with complex systems are facilitated and some unrealisable before becomes possible. It is very important that not all of the functionality needed for the experiment must be hardware-available. Part of the system can have real hardware implementation but some more complex modules can be simulated in Java code.

Thus developed, the learning materials can run on computers working with different operating systems, as Java is platform-independent programming language. Another important feature of Java applicable to a virtual experimentation is that it can run on the server side as a servlet. This enables remote control of the Unitr@in hardware through the network. All these benefits serve as motivation for development of Java interface to Unitr@in hardware.

System Architecture

The architecture developed to facilitate Java access to the hardware device is shown in Fig. 2. Lucas-Nuelle (LN) has developed Unitr@in Interface Library, which represent an API (Application Programming Interface) for managing their hardware through USB (Universal Serial Bus) or RS232 (the green rectangle in the figure). This API is based on the developed by Microsoft distributed component system (COM), which allows for any application to load any component that is contained in the COM. The component is automatically instantiated and ready to use. Each of these components (named "Interfaces") represents an individual virtual instrument like function generator, virtual oscilloscope and etc. Each of the instruments exposes methods for managing its specific functions. For example the Functional Generator (UniFuncGen) exposes methods for setting output amplitude, type and waveform of the output signal, range of the output voltage and generated frequency.

Our goal is to map the functionality of these interfaces to Java by using the JNI (Java Native Interface) standard for loading native libraries (Sun Java Runtime Environment - part). An API has been developed (yet partially) that every Java-application may include and thus enable itself to use all functionality exposed by Unitr@in. This API has two parts: native part, which communicates with COM and Java-part, which communicates with the Java-based applications. One drawback about this architecture is that it is applicable only

BEST COPY AVAILABLE

for windows-based operating systems, as far as COM is Microsoft's standard. Any change to the COM part would affect only the native part of the mapping API, but not the Java part, and all already developed applications. This makes the problem not so drastic.

Speed and Voltage Control
Applet
DC motor with transducer

Figure 3: Real experiment for dc motor controlling

Fig. 3 shows a real experiment, where the applet controls the hardware and it returns a feedback of current device behavior back to the applet for graphical interpretation of the results. The idea is to control a DC motor whose rotation speed (measured by revolutions per second) depends on the voltage applied to it. The motor generates voltage proportional to its rotation speed. This permits to maintain constant revolutions never

BEST COPY AVAILABLE

mind what is the load applied to the motor. To facilitate the task the UniFuncGen and UniMeter interfaces are used. The UniFuncGen is used to set DC voltage to the motor. The revolutions of the motor (e.g. the voltages generated by the motor) are measured by UniMeter.

The applet works in two modes.

- Manual variation of the motor's speed by means of virtual potentiometer
- Setting the required speed as numeric value

In the supply mode the voltage applied to the motor is directly supplied through a applet's scrollbar. In revolutions control mode the user set the rotational speed that should be maintained from a dc motor. In this case the applet is responsible to supply the required voltage values so that the motor revolutions are exactly as already set. This is accomplished by a continuous control of the feedback voltage. The two modes can be changed through the radio-buttons. Results are visualised graphically as a function of time. Display control of the drawings is ensured through the checkboxes.

Figure 4: Example applet

Developed Java applet ensures convenient user-friendly interface (see Fig. 4) for setting parameters of the hardware instrumentation, for controlling experiment through changing some parameters and for obtaining results from the measured device or schematic. It also provides on-line graphical interpretation of measured device characteristics.

Conclusions

The proposed Java interface to Unitr@in hardware creates new opportunities for teaching materials development. These teaching materials will combine the inherent flexibility of the Web based content delivery with the unique hands-on experience of the laboratory hardware.

The approach gives opportunity easy to set necessary parameters for controlling hardware instruments, easy to perform parameters changing and to obtain graphical result from the real experiment – all through simple Web browser. Main benefits are:

- Simplified update of the training materials– they are stored on a web server instead on students' workstations;
- Simulation of complex systems – part of the system can be implemented as real hardware and the rest can be simulated in Java code;
- Platform independence – once Unitrain drivers are ported to a new platform (e.g. Linux) the Java based training software will be readily available.

The technology also permits remote control of the hardware instrumentation and thus can support learners from a distance with ability to perform practical training in case of lack of laboratory resources.

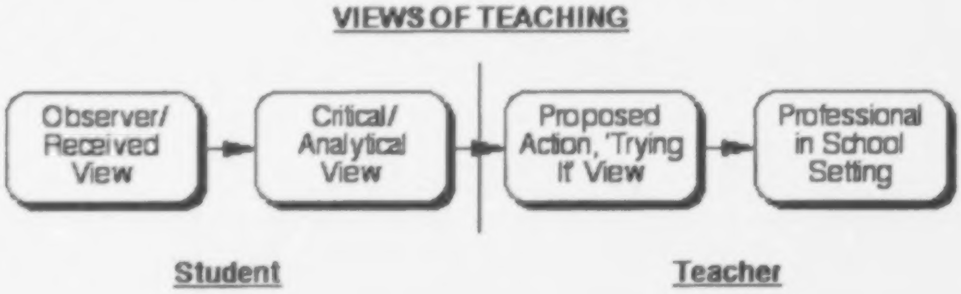
Utilizing WebCT to Monitor Pre-Service Teachers' Professional Development

The nature of teaching is evolving. Within the last twenty years, views of exemplary teaching have broadened from strictly didactic pedagogies approaches to include constructivist and student-centered approaches. The range of effective teaching practice has mirrored changes in our understanding of the psychology of learning. There has also been an effort to reach more students in an increasingly diverse student population in public schools (NCTM, 2000; NRC, 1996, AAAS, 1984) by utilizing a greater diversity of strategies. This transition has been supported and advocated by national reform efforts in mathematics (National Council of Teachers of Mathematics [NCTM], 2000) and science (American Association for the Advancement of Science [AAAS], 1984; National Research Council [NRC], 1996).

The nature of graduate educational programs addressing the needs of pre-service and in-service education professionals has also been evolving. Efforts to include and utilize technological tools and to create partnerships between institutions of higher education and local schools has been emphasized. (AAAS, 1984; Holmes Group, 1995, Bromley & Apple, 1998)

As teaching practice and teacher preparation has become more complex, the challenges that face teacher educators have also changed. Graduate education programs can no longer focus primarily on effective lecturing strategies, classroom discipline, and educational theory. Instead, these programs must assist new teachers and in-service education professionals in developing and taking on a personal identity as a reflective practioner (Kottler & Zehm, 2000). The main premise of this approach to teacher preparation is that this personal identity, based on a developing philosophy and a growing repertoire of successful practices, enables the new teacher to make decisions and design a wide range of instructional situations that engage students in meaningful learning.

In concert with this approach, a framework for preservice teacher learning has been proposed by the author (see Figure 1). The framework assumes four stages, or views of teaching, as a developmental continuum. When preservice teachers first enter teacher preparation, they often know teaching only from a student view. That is, they have been students for many years, and can identify good and bad teaching from that experience. But, they have not seen teaching from an ends-and-means perspective. They have experienced what Lortie (1975) called an "apprenticeship of observation." Thus, the first task of teacher preparation programs might be construed as developing more realistic views of teaching, through experiences that promote analysis and critique. Once preservice teachers have begun to develop more realistic views, they should be challenged to personalize their learning by positioning themselves as a teacher, and proposing what actions, principles, and guiding values they would apply in each situation. This step is seen as transitioning from student of teaching to teacher, a critical step that requires much support and encouragement as the new teacher tries on the "identity kit" of the teacher. Then, in concert with field experiences, student teaching, and induction year teaching, the new teacher incorporates this developing "teacher identity" into more and more of his/her activity, becoming a practicing professional in the school setting.



VIEWS OF TEACHING
Observer/ Received View
Critical/ Analytical View
Proposed Action, 'Trying It' View
Professional in School Setting
Student
Teacher

Figure 1: Author's framework for preservice teacher learning.

The framework is also useful in identifying in-service education professional and their professional growth as reflecting practitioners. Educational professionals who return to graduate school to pursue advanced degrees encounter novel experiences and demonstrate a transition analogous to the movement from student-centered thinking to teacher-centered thinking. Many institutions have struggled with how to gauge and document such professional development and transitions. (Holmes Group, 1995)

The focus of this research paper is upon using WebCT discussion forums as opportunities to explore professional development in pre-service teacher candidates in a graduate education program at The Ohio State University. Emphasis will be placed on how the WebCT format can augment and accurately gauge growth in pre-service teachers.

This framework underlies this paper, as we studied the development of preservice teachers and in-service education professionals pursuing advanced degrees. The majority of participants were graduate M.Ed. students in an integrated Mathematics, Science, and Technology Education teacher preparation program at a large mid-western university.

Overview

A relatively new innovation in teaching is the use of electronic educational environments to replace or supplement face-to-face, real-time instruction. Our university has recently begun to support WebCT (also known as ICT) a course environment that enables (1) management of print resources, (2) synchronous and asynchronous communication between course participants, (3) course management (such as attendance, grading, and tracking of web page) by the instructor, and (4) student presentations and posting of student work.

In this study, WebCT was utilized as a course enhancement tool for an introductory pedagogy (methods) course. This course serves both pre-service (M.Ed.) and in-service (M.A.) programs, and is seen as laying the groundwork for teacher development in these programs. Various historical, philosophical, and ethical aspects of teaching inform the course activities, and teacher participants are encouraged to develop reflective stances that will enable their learning from course experiences.

Methods and Data Sources

This study used three main data sources: participant exchanges in a WebCT threaded discussion group, teacher-created web pages (student pages) and member-checks with participants. In addition, demographic information was gathered and used to sort participants into those in the pre-service program and those who were practicing professionals.

Archived copies of the teachers' work in WebCT and (teacher-created web pages) participant interviews were examined for various features related to movement along the developmental framework.

Preliminary Results and Conclusions

The results indicated the following:

I. The WebCT forum is a viable and very helpful tool in assessing the professional development of pre-service teachers specifically for the following reasons:
   a. It allows graduate students to exchange ideas and experiences that would not be possible in other more traditional formats.
   b. It permits the instructor to monitor exchanges and the development of teacher qualities and ideas over time.
   c. Many participants, who were not vocal or expressive in class, often preferred the WebCT forum which allowed the instructors greater insight into their ideas.

2. The WebCT forum is a more authentic way of documenting changes in student thinking as they move towards the teacher "point of view."

Importance of the Study

This study has informed the use of the framework for pre-service teacher learning proposed in Figure 1 above. This study provided evidence of the difficulty of assessing professional growth along this continuum, especially in moving from student to teacher views, as well as, moving from teacher centered to student-centered practitioner. It is this shift that enables teachers to transform the way they think about teaching, from an intellectual understanding to an understanding borne of knowing by doing. This transformation is clearly complex, prematurely understood, and, by virtue of the challenge it presents, worthy of considerable careful study. If teacher educators can facilitate and support this change, they may do a better job of preparing professionals for their work in the field.

This study also explains the significance and methods college instructors of pre-service teachers may utilize the WebCT forum as a viable method of tracking professional growth that encourages and allows for the cross transmission of student experiences in their teacher preparation program.

Abstract: This brief paper argues that the concept of 'knowledge objects' can be applied to both the modular and object–based approaches within the context of online courseware design. The modular approach rests on the design principle of aggregation while the object-based approach demonstrates the principle of reduction. The impact of these differences can be seen both in the curriculum design processes and the preferred deployment methods of the courseware. The end goals of the training will be influenced by these differences as well. The points of convergence and divergence are analysed within the contextual framework of a specific subject matter domain, target audience profile and organizational structure.

Introduction

The design principles behind learning materials deployed online for corporate training purposes have been shaped by the need for modularity and reusability. This paper attempts a comparative analysis of two training solutions in terms of principles and processes of design and implementation.

Background

"If an instructional strategy does not include presentation, practice and learner guidance consistent with the knowledge and skill to be taught, then it will not teach…" (Merrill 1998). A training product, which does not teach, has no value. It is therefore reasonable to argue that a complete instructional strategy for any training product consists of a knowledge structure in line with and appropriate for the knowledge and skill being taught.

This leads us to the fact that determining **what** to teach and **how** to teach are the two most important activities of the instructional design process. Learning cannot occur if the necessary knowledge components are missing or if they are inappropriately sequenced. The instructional design process needs to focus on knowledge analysis determining the knowledge components that are necessary and appropriate for any given kind of instructional goal.

This paper uses the system of knowledge representation based on knowledge objects. (Merrill et al 1993, Merrill et al 1996). A knowledge object is a precise way to describe the subject matter content to be taught. A knowledge object is a framework for identifying necessary knowledge components. It organises a base of content resources (text, audio, video and graphics) so that a given instructional algorithm (instructional strategy) can be used to teach a variety of contents.

A knowledge object of this definition can have five major components. They are:

- The entity (module or object)
- Parts of the entity
- Properties of the entity (qualities or quantities associated with the entity)
- Activities associated with the entity (actions that a learner can perform on/with/to the entity)
- Processes associated with the entity (events triggered by an activity)

A framework for comparison

The training products, which have been taken for a comparative analysis, have the following in common:

- The instructional content is in the domain of Information Technology from the end user's point of view
- The products are deployed across the organisation – as an enterprise - wide training initiative
- Therefore the target audience for the products is heterogeneous – with diverse job roles
- The end goal of the training is a direct and positive impact towards improving performance at work.

Product Description

Product A: Excerpts from the Design Specification

Segment 1: Background
Organization X is implementing SAP in its various operational wings across the country. This effort is focused on improving their business processes in an integrated manner. There are 20,000 employees spread across the country in various functional capacities and they are expected to use SAP directly. In order to achieve this end, these employees need end-user training in the application as well as a knowledge update on the underlying business processes. E learning has been chosen as the preferred mode of training because of its flexibility (in learning time and pace) and cost-effectiveness.

Segment 2: Purpose
The purpose of the training is twofold. Firstly, a user must be able to use the SAP application software with confidence in various areas relevant to his/her job role. Secondly, the user must understand and be able to apply the underlying business processes, which drive the behaviour and components of the application software.

Segment 3: Conceptual framework
Process training focuses on descriptions of how things work. The intended learning in such contexts demonstrates in the knowledge of how things work – say, computer programmes or chemical reactions. The instructional value of process training can be summed up as follows: when an employee's work is an integral part of an organisational system, an understanding of the process offers valuable support to the performance of job tasks, motivation and overall quality of work. Process knowledge also contributes to meaningful perspectives of job roles and better application of procedures at work. The proposed solution uses this framework as a general rationale for design.

Segment 4: Instructional strategy and design parameters
Business systems depict organisational workflows. A business process consists of several stages performed by different employees or departments, which achieve an organisational goal collectively. The content in the different courses addresses the training issues in this domain in different ways.

For example, in the courses on Transactions, the smallest learning unit is a transaction. A transaction will have 'n' number of steps outlining/depicting the underlying business process. The course is the 'assignable unit' – i.e., the administrator assigns one or more courses to a user and each course consists of transactions relevant to specific job roles. In the Process Training and SAP Overview courses, the content is segmented in such a way that a course is the smallest learning unit. The content organisation structure rests on the principle of aggregation: with course as the superset with two levels of subsets – modules and transactions. The deployment rests on the 'push' strategy.

Product B: Excerpts from the Design Specifications

Segment 1: Background

Organisation X is considering the implementation of first level training in the issues relating to security issues in the handling of data/information in the electronic media formats.

Segment 2: Purpose

The purpose of the training is to create a pool of 'awareness' and knowledge base on the criticality of security related issues while handling electronic data at work. A reusable resource-base is the implicit design requirement.

Segment 3: Conceptual framework

There is no sequence evident in the information architecture. The linkages do not suggest a structural hierarchy. It is reasonable to assume therefore that the user groups may want to dip into this (information pool) resource at different times and more such information chunks may be added to the pool. An object-oriented paradigm suits this end very well. This results in the development of adaptive learning systems that can assemble content to meet the learners' needs 'on the fly'.

Segment 4: Instructional strategy and design parameters

Object –based design, which stems from a bottom up approach of reducing the instructional content to the smallest, self-contained entity.

Design parameters

- The notional learning time per object (variable)
- The logical information architecture within the object and its linkages or dependencies with other objects (much like the properties of an atom and a chaining of atoms)
- The logical structure for content organisation within the object

Object type and description:

The chosen object type for this product is Generative-instructional. In this type, the logic and structure for combining media elements or other object types (if applicable) and evaluating student interactions with these combinations support the instantiation of abstract instructional strategies. For example: 'remember and perform a series of steps' or 'understand a set of rules/policy regulations and apply them at work'. The content organisation structure rests on the principle of reduction. Each object is a self-contained instructional unit with direct or indirect or no linkages to the other objects in the domain. The deployment rests on a 'pull' strategy.

The table below summarises how the components of a knowledge object can be applied to both the products.

Component Description	*Product A*	*Product B*
The entity	Course	Object
Parts of the entity	Modules and transactions	Smallest unit with single point access
Properties of the entity (qualities or quantities associated with the entity)	One or many modules and one or many transactions	(i) Learning Objectives (outcomes-based, set at 'recall' level) (ii) Core instructional content – logical structure defined by questions such as 'How to... What is...where is..."Core content falls under the categories of facts (definitions and descriptions), Dos and don'ts etc. (iii) Questions mapping to the learning objectives. Note: A minimum of 1 and

		maximum of 'n' objectives and questions per object
Activities associated with the entity (actions that a learner can perform on/with/to the entity)	'Show and Tell' and 'Try': guided practice	Aided recall of instructional content through engaging in application-oriented tasks.
Processes associated with the entity (events triggered by an activity)	Learning by practice and aggregation	Learning by practice and selective association

Table 1: A comparative analysis of design components

Analysis

The principal differences in the design approaches described above can be categorised in terms of

- Instructional design and content organisation structures (aggregation versus reduction)
- Deployment strategy ('push' versus 'pull')
- Levels of reusability (intermediate versus absolute)

The comparative analysis demonstrates how these divergent design approaches can be employed to deliver instruction meeting different end goals despite the aspects of convergence in the subject matter and target audience profile. The manner in which the differences will be borne upon the strategic outcomes will be discussed in the presentation.

In sum, it is reasonable to argue that the more traditional, modular approach to course design is as valuable to the context of self-paced online courseware development as the more recent object-based approach. The modular approach follows a 'top down' model while the object based design draws on a 'bottom up' model in terms of curriculum design. This difference has a significant impact on the relative ease with which one can add to or modify the instructional content. This in turn is chained to the decisions of deployment.

Conclusion

The comparative analysis of two training products in the corporate training context attempts to highlight the points of convergence and divergence between the design approaches resting on the principles of aggregation and reduction respectively.

If reusability is to be viewed as a continuum the two design approaches are differentially weighted and placed. However, absolute reusability as a characteristic evident in object-based design approach is most suited to the 'pull' strategy of deployment while an intermediate level of reusability evident in a modular design structure meets the goals of a 'push' strategy of deployment. Therefore the design approaches offer mutually exclusive advantages to the training context.

ONLINE VIRTUAL TUTORIALS: INCREASING ACCESS TO PEER TO PEER TUTORING

Ray Walshe
Language and Intelligence Research Group, Department of Computing, Dublin City University, Dublin
IRELAND
E-Mail: Ray.Walshe@Computing.DCU.ie Web: http://www.computing.dcu.ie/~ray

Abstract: With the continuing increase in class sizes of undergraduate computer science degrees, it is becoming more difficult to provide additional tutoring resources on an individual basis to students. Although peer tutoring is employed in a structured timetable to aid undergraduates, some questions remained unanswered in the time allowed and a bigger problem may be that some questions are just not asked. To address this issue, a discussion forum was set up which facilitated anonymous logins where students could post questions outside of scheduled tutorials and have them answered by fellow students, tutors and lecturers. This paper describes the system and some of the results obtained.

Keywords: Peer-to-Peer Tutoring, Virtual Tutorials, Online Virtual Classroom.

1 Introduction

As class sizes increase in undergraduate computer science courses it has become more difficult to provide adequate tutorial assistance to students. In large lecture groups, individual students become anonymous and feel lost. Larger lecture sizes have led to larger tutorial classes and there is a limit to the number of full time academics and post-graduate students that are available to facilitate smaller tutorial groups. Peer tutoring has been introduced where using undergraduate tutors the tutorial group size has been reduced to 10 [1]. Using peer tutoring, second year students who have achieved excellent results are employed to provide tutorial assistance in a lab-based environment. Employment of this system over the last two years has shown a marked improvement in lab exam results. However, there still remained the case where some students felt they were not able to engage at this micro level and wished for the mask of anonymity so that they could ask questions that may be regarded as trivial or embarrassing.

2 Course Structure

The course in question is a first year Computer Architecture course that is delivered across two semesters to a lecture group size of 300+ students. Additional large tutorials are given at intervals during the semester. There are lab-based exercises which have to be performed where the labs can accommodate 45-65 students per lab to facilitate 150+ students at any one time. Within these labs of 45-65 students are sub-groups called "bays" where one peer tutor is assigned to a bay that contains at most 10 students. These laboratories are located on three different floors so just physically getting around them all during a particular lab session can be quite demanding. The discussion forum where students can air any problems that may arise at any time proves useful here as means of asking questions. Other students, tutors or staff can then answer these questions.

2.1 The Lab Tutor

The tutors come from a panel of 60 second-year students who would be those at the top of their class based on the examination results. The number is in fact, well over our requirements as a max of only 30 are required for a given session which makes for a 10:1 student to tutor ratio. Becoming a lab tutor is a significant step for second year students. It challenges them to take on a new role and responsibilities toward their fellow students that may seem strange at the outset. To help them manage the adjustment a one-day seminar is held at the beginning of the year to look at the issues arising from the job. A very important part of the lab tutor's job is the Feedback Form. This is an application developed last year in the faculty that has proved important as part of the lab tutor's work.

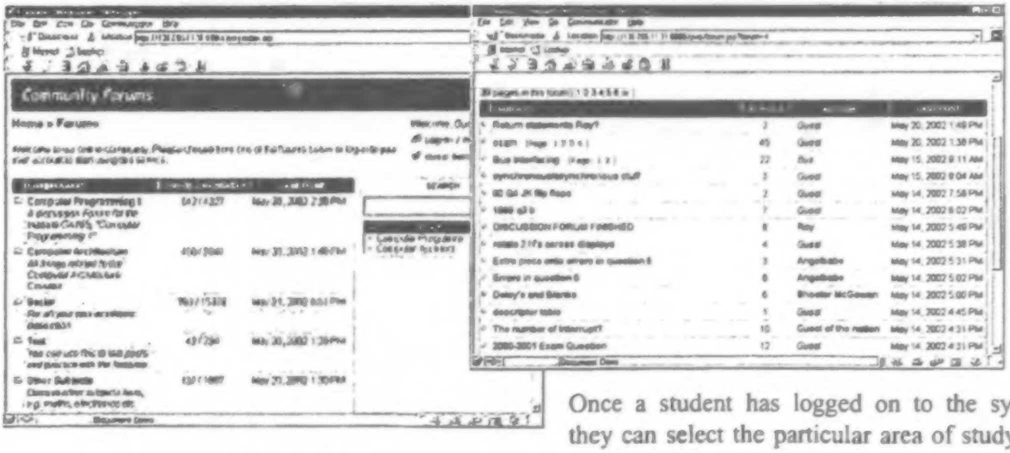
The feedback form fulfills a number of important tasks. It can help to identify problem students sooner. The 10:1 ratio means that over the course of a semester the tutor can get to know each student individually. This relationship is at the core of the success of the system so far. Many tutors begin to take a personal interest in their tutees and are delighted when they manage to do well in the exams. Conversely if a student is having trouble, the tutor can be the first to spot it and take remedial action. The feedback given by tutors is very valuable for lecturers. At the end of a lab session, a lecturer can log on immediately and read the tutors comments. This can give the lecturer a very good idea of how the material is being interpreted. The material can then be enhanced accordingly.

3 Discussion Forum System

Jive is forum software that allows dynamic, threaded discussions on web-sites. The Jive source code is open, which makes it easy to customise and integrate it into existing sites. The forum leverages the architecture of server-side Java. Jive's clean, object-oriented design is extensible, scalable, and secure. The recent widespread availability of server-side Java enabled web-servers means that it will run almost anywhere. An arbitrary number of filters can be applied at runtime to provide advanced forum services. Some filters examples include syntax highlighting of Java code, translation from one language to another, and profane language filtering.

The discussion forum is accessible through a web link on the course homepage. Students can logon to the discussion forum using a self-generated username or by signing on as guest. The guest login facilitates anonymous posting of questions/answers. The forum is running 24 hours per day and 7 days per week and is monitored periodically by staff and tutors between the hours of 8:00 a.m. and 10:00 p.m. when staff /tutors may be on campus.

The two main forums that were provided were labelled Computer Architecture and Computer Programming. Additional forums were also provided for social interaction purposes and other academic disciplines.

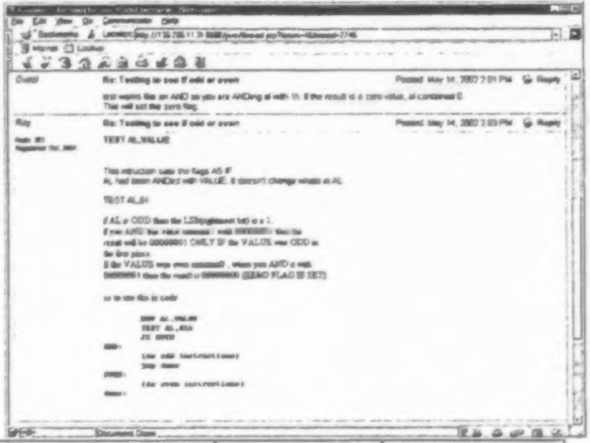


Once a student has logged on to the system they can select the particular area of study and

BEST COPY AVAILABLE

examine all topics relating to their area of study that have been posted. Once a particular topic is selected they can then view all questions and answers within that topic.

At this level questions can be asked and answered with or without anonymity.



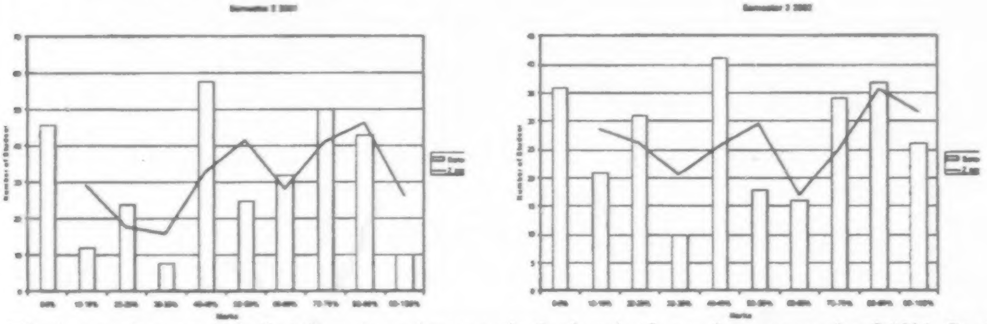
4 Results

The board has been very successful in fostering peer to peer interaction between students and tutors. The provision of a social forum encourages the students to talk about every day topics and allowed students to become familiar and comfortable with using the forums.

Usage statistics for forum

Period of Use	*Topics Created*	*Messages Posted*
Discussion Board All Year	2124	23793
Architecture Forum Semesters 1 and 2	450	2041
Architecture Forum 3 **day period**pre End-of-Term Semester 1 Exams	87	392
Architecture Forum 3 **day period**pre End-of-Term Semester 2 Exams	54	306

Exam Results 2001-2002



The interesting result is that there is an increase in the levels above the pass mark of 40%. Students are achieving higher marks on the paper although the year-on-year pass rate has only marginally increased. The increase in overall mark per student is mostly noted in the lab element of the course where the largest volume of discussion was centred.

5 Conclusion and Further Work

By combining the close monitoring of lab assessment through peer tutoring and feedback and by providing academic support via the discussion forums, a higher pass rate and level of award has been achieved. This system is being modified at the moment to allow access to each individuals performance relative to interaction with the discussion forum. Here we hope to identify when/why a particular student will avail of the discussion board and the change in performance levels achieved in exams post interaction.

Student Perceptions Toward Using Instant Messenger to Facilitate *e*Learning Online Interaction in Conventional Versus Virtual Graduate Classrooms

Lih-Ching Chen Wang
Department of Curriculum and Foundations
Cleveland State University
2121 Euclid Ave.
Cleveland, OH 44115, USA
l.c.wang@csuohio.edu

Abstract: This study will investigate student perceptions of two different methods of online interaction in graduate educational technology coursework. All students will use an instant messenger (IM) program to facilitate online interaction between student/instructor and student/student. One group will be required to participate in IM topic-discussion-online in the conventional classroom. The other group will be required to participate in IM topic-discussion-online in the virtual classroom. Both groups will undergo a period of required access to office-hours-online, then be offered the option of continuing to use office-hours-online for the remainder of the semester. Student perceptions toward topic-discussion-online and instructor's office-hours-online between these two groups will be studied, along with their relative perceptions toward online interaction in general.

Introduction

More and more students and faculty are using instant messenger (IM) programs to facilitate quick synchronous online text interaction because IM is faster than other asynchronous electronic interaction media such as email and voice mail messaging. The current most popular, fast, easy, and free IM programs used in academia include AIM (AOL [America Online] Instant Messenger) and MSN (Microsoft Network) Messenger. Both programs provide online interactive functions such as instant online chatting, instant message exchange, instant online calling, buddy group creation, file and image exchange, and so on. The online chat and message exchange functions will be used primarily for this study, along with the ability of IM users to set up and use their own customized discussion groups. Such facilities have great potential in facilitating class synchronous online interaction between the student and instructor and student and student.

Interaction is a powerful force in education. "Online interaction" has recently been used as a factor in assessing a variety of distance education activities by diligent researchers. Wojahn (1994) used it in examining men's and women's online communication behaviors on four electronic bulletin boards and compared them to face-to-face communications. Warschauer (1997) employed it in assessing computer-mediated interaction in a second language based on a sociocultural analysis of the relationship among text, talk, and learning. Hollenbeck (1998) used it in assessing the Internet as a place for fostering democracy in computer conferencing. Essex and Cagiltay (2001) used it in evaluating the feedback of "distressed" students on a Web-based distance education course. Nevertheless, none of these studies have yet used IM to investigate the effectiveness of online interaction.

How can "online interaction" be assessed appropriately in higher education? In 1987, Chickering and Gamson created "Seven Principles for Good Practice in Undergraduate Education." These principles include (1) encouraging contacts between student and faculty, (2) developing reciprocity and cooperation among students, (3) using active learning techniques, (4) giving prompt feedback, (5) emphasizing time on task, (6) communicating high expectations, and (7) respecting diverse talents and ways of learning. Since that time they have been used to assess a variety of arenas in higher education, particularly in the area of instructional technology (for example, see Chickering & Ehrmann, 1996).

The purpose of this study is to investigate whether IM programs can be used to facilitate the online *e*Learning interaction both in conventional and virtual classrooms. Student perceptions toward an IM program applied in class topic discussions will be the focus for the investigation. The first (i.e. encourages contacts between student and faculty), second (i.e. develops reciprocity and cooperation among students), and fourth (i.e. gives prompt feedback) principles among the seven principles of good practice in higher education will be the focus of assessment in the study.

Design and Procedure

Subjects will be graduate students from two sections (conventional versus virtual) of an educational technology class taught at a midwestern urban state university during the Fall 2002 term. The anticipated number of participants is approximately 40. They are mostly Pre K-12 educators.

One section of the class will employ traditional classroom instruction, and will serve as the control group. The other section is Web-based (with the exception of a single initial class meeting in person) and will serve as the experimental group. The course content, instructor, and calendar for both sections are identical.

Both classes will receive direct instruction in the use of an instant messenger (IM) program, and both groups will be required to carry out a planned series of class discussions (centering around major chapter topics) entirely in the IM environment. Both groups will also be required to use the IM-based office-hours-online process for all contacts with the instructor (outside of class) during the first three weeks of the semester, after which all students may choose freely to use either office-hours-online or more traditional means of contacting the instructor.

This is a study of online interaction, and two aspects of online interaction will be involved. The first is that of topic-discussion-online. Both groups will discuss the same topics during the same time frame, with the same preparation and supervision, within the IM environment. The only difference between the two groups will be that one will meet entirely in a traditional classroom setting, and the other will meet (almost) entirely in an online setting. The discussion topics, guidelines and schedule will be provided on the course syllabus for both groups.

The second aspect is that of office-hours-online. Both groups will receive the same direct instruction in the use of IM, and both will be required to use only this method for contacts with the instructor outside of class during the first three weeks of the semester. After the initial three-week period, both groups will be allowed to use either online or other means (e.g. personal contact, telephone, fax, E-mail, etc.) to confer with the instructor. Data will be collected on the issue of which students from which group make which choices in this matter. All students will be told that their participation will be part of their coursework but their grades will not be affected by participation in the experiment.

Research Questions

Within the context of IM-based *e*Learning, four research questions are proposed: (1) Is there a difference in student perceptions toward the IM online interaction methodology during topic-discussion-online in terms of "developing reciprocity and cooperation among students" between conventional and virtual classrooms? (2) Is there a difference in student perceptions toward the IM online interaction methodology during the office-hours-online in terms of "encouraging contacts between student and instructor" between conventional and virtual classrooms? (3) Is there a difference in student perceptions toward the IM interaction methodology during the office-hours-online in terms of "giving prompt feedback" between conventional and virtual classrooms? (4) Which group of student has more "participation frequency" in the office-hours-online between conventional and virtual classrooms?

Data Sources

All students will complete two questionnaires, one a pretest and the other a post-test. The pretest will collect two types of information. One set of questions will address students' prior IM experience and experience with online group discussions; the other will address their perceptions in specific areas dealing with the research questions of this study. The post-test will collect only information on student perceptions, using the same questions used in the perception portion of the pretest.

The first research question deals with student perceptions of topic-discussion-online. The questions in this area will deal with the principle of "developing reciprocity and cooperation among students."

The second, third and fourth research questions all deal with student perceptions of office-hours-online. For the second, questionnaire items will address the principle of "encouraging contacts between student and instructor." For the third, they will address the principle of "giving prompt feedback."

The fourth research question addresses the "participation frequency" between conventional and virtual groups during the instructor's office-hours-online. The data source for this question will not be the pretest or post-test, but will be the instructor's frequency count of office-hours-online participation by class section.

All the experimental material delivery, survey, and data collection will be administered online. An Analysis of Variance (ANOVA) model will be used to test the significance of the differences in students' perceptions in specific areas dealing with the research questions of this study. The three principles (addressed in research questions one to three) and the "participation frequency" (addressed in research question four) are the primary dependent variables while the class formats in using IM program (IM in conventional classroom vs. IM in virtual classroom) are the primary independent variable.

Educational Importance of the Study

The study is educationally significant in a number of ways. It is one of the few studies investigating the differences between the ways in which traditional and online students perceive specific aspects of online interaction. It is also one of the few studies to investigate specific classroom applications of an IM program, both for instruction and for individual contact between students and instructor. Knowledge derived from this study can help us all make better informed decisions about the situations in which it may be pedagogically appropriate to employ online discussions or online office hours, either in an *e*Learning situation or even within the context of a class which is otherwise largely traditional. Should students turn out to regard either (or both) aspects of IM as being at least the equal of more traditional approaches, this information can help us to move toward an optimal balance of traditional and online methodologies for instructional purposes.

Electronic Cognitive Apprenticeships: Examining Novice and Advanced Learners' Perceptions of Case-Based Collaborative Learning

Sung Hee Park

baih@purdue.edu

Ling Wang
Department of Curriculum and Instruction
Purdue University, USA
wang23@purdue.edu

Abstract: This study examined novice and advanced learners' perceptions of case-based collaborative learning as they participated in an electronic apprenticeship environment during a semester-long course. Novice and advanced learners analyzed a set of instructional design case studies. Novice learners also developed instructional design projects with feedback from the advanced learners. By engaging in joint case analyses and design reviews both groups of learners developed specific perceptions of case-based discussions and project review apprenticeship experiences. Recommendations for the future format of this course and educational implications of such a course were also addressed.

Theoretical Framework

According to Collins, Brown, and Holum (1991) an apprenticeship environment provides students with opportunities to apply expert problem-solving strategies. In a cognitive apprenticeship environment, the goal is to make visible and explicit complex thinking and problem-solving strategies that experts use in particular domains. By combining six distinct teaching strategies (modeling, coaching, scaffolding, articulation, reflection, and exploration), students can conceptualize their knowledge and use that knowledge in a variety of settings (Collins, Brown, & Newman, 1989).

Supporting these methods of cognitive apprenticeships is the concept of authentic activity—the use of ordinary practices of a given culture as a basis for learning (Brown, Collins, & Duguid, 1989). One promising approach to initiating authentic, contextual learning is case-based instruction.

Case-based instruction has been used in professional preparation programs to make a bridge between classroom and field. Recently case-based instruction was introduced into the instructional design field (Ertmer & Quinn, 1999). The effective use of cases requires students to apply critical thinking to a problem situation to analyze the situation and recommend realistic solutions through better understanding (Ertmer & Russell, 1995; Shulman, 1992; Wright, 1996).

Flynn and Klein (2001) examined the role of group discussion in case-based instruction. Participants working in groups performed better while analyzing cases than those who worked alone. Other researchers (Griffith & Laframboise, 1997; Levin, 1995) found that, for experienced learners, discussion appeared to act as a catalyst for reflection based more on personal experiences than on theory and course content, while for less experienced learners, discussion appeared to allow them to clarify or elaborate their understanding and increase their perspectives on the issues in the cases.

Simply stated, case-based instruction becomes more effective when learners at different levels work collaboratively in an apprenticeship environment. However, previous research focused more on the growth in novice learners' problem-solving expertise and their benefits from this learning experience. Little research has explored how advanced learners perceived the collaborative experience with novice learners. Therefore, it is important to examine how both novice learners and advanced learners perceive the benefits of case-based instruction facilitated in an apprenticeship environment.

Purpose

This study examined novice and advanced learners' perceptions of case-based collaborative learning during one semester in which they participated in an electronic apprenticeship environment. Specifically, the research questions included:

- What are novice and advanced learners' perceptions of case-based collaborative problem-solving activities?
- What are the novice and advanced learners' perceptions of instructional design project reviews in electronic cognitive apprenticeship environment?

Methods

Graduate students (n=19) at one Mid-western university enrolled in an introductory instructional design course (classified as novice learners) and graduate students (n=10) from another Mid-western campus enrolled in an advanced instructional design course (classified as advanced learners) participated in a semester-long study. Three graduate students from the latter group conducted the research.

Qualitative data were gathered from three sources: 1) discussion board postings revolving around case study discussions and instructional design project reviews collected from all participants, 2) open-ended surveys from seven advanced learners and seven novice learners, and 3) follow-up interviews conducted with seven advanced learners and three novice learners.

Throughout the semester, participants analyzed and discussed 10 case studies via an online discussion board and videoconferencing. Online case discussions employed different types of setups including role-play, small group discussions, debate, and so on. A total of 889 messages were posted when participants discussed these cases.

Novice instructional design students created an instructional design project and the advanced learners played the role of mentors to review novice learners' projects. They exchanged their opinions and ideas via online discussion board and synchronous chat rooms. At the end of the course, seven advanced learners and seven novice learners completed an open-ended survey that included 8 questions concerning the activities they participated when taking the course (e.g. Discuss your ideas about our collaboration with HRD 406 students, including the benefits/challenges associated with providing feedback on their design projects). In addition, the researchers conducted follow-up interviews with seven advanced learners and three novice learners. The interviews lasted about 30 to 40 minutes and 10 questions were asked (e.g. What benefits do you perceive of the collaborative discussion of ID cases, especially in terms of how the discussions helped develop your skills and knowledge of ID?). With their permission, the interview data were tape-recorded and then transcribed.

A constant comparison analysis method (Guba & Lincoln, 1989) was used to generate the categories and patterns from qualitative data to determine the advanced and novice learners' perceptions of case-based collaborative learning in the electronic cognitive apprenticeship environment.

Results and Discussion

Case-Based Collaborative Discussion

The advanced and novice learners had similar perceptions of the benefits of the case discussion. They agreed the strongest benefit was that they could share different perspectives and viewpoints with each other and that it deepened their understanding of instructional design. Discussing the cases provided them with the real world ID experiences and they could learn from the mistakes of the case players. Two advanced learners made the following comments on the benefits:

> Be able to get different viewpoint on a problem…I am bound to hear something I wouldn't have thought by myself, I wouldn't have considered then by that I've learned something new.

> The collaborative discussion deepened my understanding to analyze the cases in the real world. First, the benefit is expanding my understanding of the case. Second, it makes me feel more interested in the class and also in the (collaborative) discussion.

One novice learner stated:

> Learning from others' mistakes should help in avoiding the same mistakes, whether the problem was the original mistake or the way it was handled.

For case discussions, a big weakness that the advanced learners reported was the repetition of discussion content via online discussion, videoconferencing and in-class discussion. One advanced learner commented:

> The online discussions were productive but repetitive. I think dedicating so much time online and then in-class was too much time.

Compared to the advanced learners, the novice learners felt confused by the value of the cases. Since they were in the introductory course of instructional design, studying the instructional design model and simultaneously discussing those cases made them feel confused. One novice learner stated: "I thought they [case discussions] did not fit in with the other work we did in this class." The novice learners also addressed the redundancy and quality of online postings: "Students only repeating and agreeing with information already posted."

Project Review Apprenticeship

Compared to benefits of the case discussions, the advanced and novice learners perceived the benefit of the project review quite differently. The advanced learners reported that the project review helped them reinforce and refresh their knowledge of ID. This also gave them an opportunity to think about ID process from the perspective of an evaluator. Furthermore, this process reflected the realistic ID world experience. As one advanced learner noted:

> This is more like realistic ID world… going through without any [subject matter] knowledge. It's very beneficial to see the product from the beginning…and the way we worked in the place where we were presented with problems and did not have SME [all made the experience resemble real world ID].

The novice learners liked the collaborative work with mentors and peers. With the feedback from them, they could improve and revise their ID project. One novice learner described:

> [I was] satisfied with most comments and recommendations. Having never done ID before, I benefited from someone looking at the issue from a different and alternative perspective and offering those types of suggestion.

For the instructional design project review, the advanced learners thought that projects submitted by some novice learners did not meet the requirements of the project assignment made the project review incomplete and unsatisfactory. Moreover, because the advanced learners critiqued only three of the six projects, they were not able to form a whole picture of the novice learners' instructional design projects. They also worried that the novice learners sometimes just took their words as right without arguing and challenging.

The novice learners considered time to be a limitation of the fulfillment and collaboration in project review. One made comments as such: "We don't have enough time to stay in touch. We don't have enough time to collaborate, just a little bit some time online, you know."

Recommendations

The participants suggested that both technical issues and course design issues should be considered when offering such a course in the future.

For the technical issues, the participants suggested that a technical coordinator be used to facilitate the video conferencing in order to make sure the conferencing went on smoothly. Another issue the participants addressed was that, before the video conferencing session, the video and audio quality should be double checked so that quality issue would not be an interruption to the conferencing. The participants also recommended that the learners taking the course should well prepare themselves for a course of such a format by making sure they have access to the Internet either at home or at a place convenient for them.

For the course design issues, the participants specifically addressed issues concerning online discussion, case studies, course syllabus, course participants, and course assignments.

For online discussion, the participants suggested the use of smaller group activities so that the online discussion would be more manageable. They also expressed the need for a facilitator or specific guidelines. As to the cases used for the course, they suggested "the cases used in the course should be made sure updated to the date and explicitly written."

The participants made some suggestion to the arrangement of the course syllabus. They suggested the use of video conferencing at the early stage of the course in order to help participants put faces with names. They also suggested the use of one format of media in each week or the use of different format of media for each case study. In addition, they believed that more cases could be discussed in one week. For example, an advanced learner made such a comment:

> We could have discussed more cases in one week and so hit more topics of ID… we don't have to do one case on-line, then in class, and then on polycom.

Furthermore, they suggested, if possible, more frequent contact or face-to-face communication between participants should be arranged. For example, another advanced learner commented:

> I like it [videoconferencing] very much because it was more personalized. Polycom is a great technology. It allows more freedom in the discussion and does not try to bias the discussion.

Finally, as to who should participate in such a course, they suggested that the two sites for the collaborative learning be of similar size and especially the advanced learners wanted to discuss with learners who had a similar level of ID skills and knowledge.

Educational Significance and Implications

The results of this study suggested both benefits and challenges of case-based discussion and project review apprenticeship for both advanced and novice learners. The recommendations made by both advanced and novice learners from their specific standing points in the apprenticeship environment highlighted the importance of making necessary changes and improvements to the format and design of such an ID course of collaborative learning when it is offered in the future.

Impact of Vicarious Learning Experiences and Goal Setting on Preservice Teachers' Self-Efficacy for Technology Integration

Ling Wang
Department of Curriculum and Instruction
Purdue University, USA
Wang23@purdue.edu

Abstract: This pilot study was designed to explore how vicarious learning experiences and goal setting influence preservice teachers' self-efficacy for integrating technology into the classroom. In this pilot study, twenty students from the Teacher Education program at a Mid-western university participated and were assigned into four experimental conditions. Results showed the individual and collective effects of vicarious experiences and goal setting on the participants' judgments of self-efficacy for technology integration. More data were simulated based on the result of this pilot study to detect the effect of vicarious learning experiences and goal setting when the sample size was 80 participants.

Theoretical Framework

Despite the increased availability and support for computers (Zehr, 1997, 1998), relatively few teachers have fully integrated computers into their classroom teaching (Marcinkiewicz, 1996). There is substantial evidence to suggest that teachers' beliefs in their capacity to work effectively with technology, that is, their computer self-efficacy, is a significant factor in determining patterns of classroom computer use (Oliver & Shapiro, 1993). The studies on teachers' self-efficacy beliefs provide sufficient reason to undertake further investigations in this area and to consider approaches to teacher education and professional development that might be effective in increasing self-efficacy for teaching with technology.

Bandura (1986) identified four sources of information used to judge self-efficacy: successful performance attainment; observing the performances of others (vicarious learning); verbal persuasion indicating that one possesses certain capabilities; and physiological states by which one judges capability, strength, and vulnerability. Although performance accomplishments are considered to be the most robust source of self-efficacy information, vicarious learning also provides a powerful source (Bandura, 1986, 1997). That is, viewing others successfully accomplish a particular task can increase one's perceptions of others' efficacy as well as one's own self-efficacy for similar tasks (Bandura, 1997). The effects of vicarious learning merit further examination.

While novice learners can acquire skills and strategies from social modeling, when performing independently they are likely to over- or underestimate their capabilities (Schunk, 2001). However, by making learning goals explicit, students' judgments of progress, as well as their judgments of self-efficacy, increase in accuracy and strength (Schunk, 2001). Goals can motivate behavior and inform people about their capabilities (Bandura, 1997; Schunk, 1996). When students are given or establish a goal, they may experience a sense of efficacy for attaining it.

Based on the literature described above, this study examined the impact of vicarious learning experiences and goal setting on preservice teachers' self-efficacy for technology integration.

Purpose

This study explored how vicarious learning experiences and goal setting influence preservice teachers' self-efficacy for integrating technology into the classroom. Specifically, this study was guided by the following research question:

What are the individual and collective effects of vicarious experiences and goal setting on preservice teachers' judgments of self-efficacy for technology integration?

Based on the self-efficacy literature described above, it was hypothesized that preservice teachers who engaged in vicarious experiences, related to successful technology integration, would experience a significantly greater increase in judgments of computer self-efficacy than those who did not engage in these vicarious experiences. Furthermore, it was hypothesized that preservice teachers who engaged in goal setting, related to increasing their technology integration skills, would experience a significantly greater increase in judgments of computer self-efficacy than those who did not engage in goal setting. Finally, it was hypothesized that preservice teachers who engaged in vicarious experiences and goal setting would demonstrate the greatest increases in judgments of computer self-efficacy compared to students who engaged in either one of these conditions alone.

Methods

Participants were solicited from a four-week three-credit educational technology course at a large Mid-western university. They were sophomores in the Teacher Education program and their age range was from 18 to 25.Thirty-one students signed the informed consent form and agreed to participate, but only twenty of them finally showed up in the study. The thirty-one participants were randomly assigned into four experimental conditions. The numbers of participants who finally showed up for the four experimental conditions were 6, 6, 4, and 4 (Note: The unequal group size was due to the dropouts from the study).

A 2 x 2 (Vicarious Experiences: use of VisionQuest software [Note: VisionQuest is an instructional tool designed to provide opportunities for users to explore models of effective technology integration] vs. no use of VisionQuest software x Presence of Goal Setting: goal setting vs. no goal setting) mixed factorial research design was used to examine how vicarious experiences and learning goals individually, as well as collectively, impacted preservice teachers' judgments of their computer self-efficacy. These independent variables were combined to form four experimental conditions: (a) NVQ / NG: no use of VisionQuest software and no learning goals (also defined as control group), (b) NVQ / G: no use of VisionQuest software but with learning goals, (c) VQ / NG: use of VisionQuest software but without learning goals, and (d) VQ / G: use of VisionQuest software and with learning goals.

Data Collection and Analysis

Demographic data, including information about gender, class, and previous computer experiences were collected from all participating students. A Likert-style survey measuring participants' self-efficacy served as the primary data source and was administered at the end of each experimental condition. The survey was constructed by the researcher after consulting with content area experts. The survey included 21 items regarding participants' confidence for technology use (see the attachment). The participants were asked to rate their level of agreement (from 1-strongly disagree to 5-strongly agree) with statements related to their possession of confidence regarding technology use (e.g., "I feel confident that I understand computer capabilities well enough to maximize them in my classroom." "I feel confident I can regularly incorporate technology into my lessons, when appropriate to student learning."). Cronbach alpha was calculated to determine the reliability of the survey items. The alpha coefficient was 0.9293.

For the groups that engaged in vicarious experiences, participants explored the VisionQuest CD-ROM and observed the exemplar teachers' technology use and classroom management strategies. For the groups that engaged in learning goals, participants were given, at the beginning of the experiment, 3 to 5 specific goals related to learning about technology integration.

Means and standard deviations for each experimental condition were calculated. Two-way ANOVA was used to determine the main effects of IV_1 (vicarious learning experiences through viewing VisionQuest CD-ROM) and IV_2 (learning goals) and the interaction of IV_1 and IV_2. One-way ANOVA was then used to determine which of the four experimental conditions was significantly different from which.

Results and Conclusion

The four experimental conditions had the following means and standard deviations: VQ / G (mean= 4.55, SD=0.33); VQ / NG (mean=4.30, SD=0.41); NVQ / G (mean=4.24, SD=0.52); and NVQ / NG (mean= 3.57, SD=0.14).

The F value (F=5.57, p=0.0082, df=3, 16) from the two-way ANOVA indicated that there was at least one main effect of the two factors was significant. Then when examining the F values for each of the two factors and the interaction of the two factors, the researcher found that the vicarious learning factor had a significant main effect on the self-efficacy (F=9.18, p=0.0080, df=1, 16), the learning goals factor also had a significant main effect on the self-efficacy (F=6.06, p=0.0256, df=1, 16), but the interaction of the two factors was not significant (F=1.48, p=0.2407, df=1, 16).

The F value from the (F=5.57, p=0.0082, df=3, 16) from the one-way ANOVA indicated that the variable—different conditions of the experiment—had a significant effect on the self-efficacy. When examining which conditions were significantly different from which conditions, the researcher found that the following between-condition differences were significant at the 0.05 level: VQ / G – NVQ / NG (the mean difference=0.98), and VQ / NG – NVQ / NG (the mean difference=0.73).

This study was the pilot study for the researcher's dissertation research. From the results of the data analysis, it can be concluded that the preservice teachers who engaged in vicarious experiences, related to successful technology integration, experienced a significantly greater increase in judgments of computer self-efficacy than those who did not engage in these vicarious experiences. Also, the preservice teachers who engaged in learning goals, related to increasing their technology integration skills, experienced a significantly greater increase in judgments of computer self-efficacy than those who did not engage in learning goals. In addition, the preservice teachers who engaged in vicarious experiences (with or without learning goals) demonstrated significant increases in judgments of computer self-efficacy compared to those who engaged in neither of the two conditions. However, the preservice teachers who engaged in learning goals alone did not demonstrate significant increases in judgments of computer self-efficacy compared to those who engaged in neither of the two conditions. Similarly, the preservice teachers who engaged in both vicarious experiences and learning goals did not necessarily demonstrate significant increases in judgments of computer self-efficacy compared to those who engaged in either of the two conditions alone.

Because this was a pilot study with only twenty participants, the small sample size of the study could be a factor affecting the results (or at least part of the results). Therefore, the researcher simulated some data based on the means and standard deviations of the four experimental conditions of the pilot study. After simulation, the sample size was enlarged to 80 participants and 20 participants in each of the four conditions.

The F value (F=27.5, p<0.0001, df=3, 76) from the two-way ANOVA indicated that there was at least one main effect of the two factors was significant. Then when examining the F values for each of the two factors and the interaction of the two factors, the researcher found that the vicarious learning factor had a significant main effect on the self-efficacy (F=40.46, p<0.0001, df=1, 76), the learning goals factor also had a significant main effect on the self-efficacy (F=38.83, p<0.0001, df=1, 76), but the interaction of the two factors was not significant (F=3.21, p=0.0773, df=1, 76).

The F value from the (F=27.5, p<0.0001, df=3, 76) from the one-way ANOVA indicated that the variable—different conditions of the experiment—had a significant effect on the self-efficacy. When examining which conditions were significantly different from which conditions, the researcher found that the following between-condition differences were significant at the 0.05 level: VQ / G – VQ / NG, VQ / G – NVQ / G, VQ / NG – NVQ / NG, NVQ / G – NVQ / NG, and VQ / NG – NVQ / NG.

With the findings from the simulated sample size, the researcher concluded that the preservice teachers who engaged in both vicarious experiences and learning goals did demonstrate significant increases in judgments of computer self-efficacy compared to those who engaged in either of the two conditions alone, in addition to the significant increases detected in preservice teachers' judgments of computer self-efficacy when only one condition was present.

Educational Implication

The results of this study will contribute to the existing body of literature in two significant ways: (1) by describing how preservice teachers benefit from observing teacher models presented via multimedia case examples, such as those featured on VisionQuest, and (2) by describing how preservice teachers benefit from learning goals for technology integration. From an instructor's perspective, the use of electronic models via multimedia and the incorporation of learning goals can positively impact the authentic nature of a course and simultaneously increase the confidence and integration beliefs of students. This type of modeling and goal setting can help preservice teachers develop a vision for what technology integration looks like in real classrooms as well as strategies for implementing those visions.

Abstract: This paper is a report on the findings of a study conducted on a graduate level online course. We used discourse analysis techniques to examine the chat transcript of texts for evidence of the relationship among gender, discourse style, and equal participation. We also conducted online observations and surveyed participants' perceptions on their online discussions. Findings from all sources do not reveal any significant gender differences in the online discussions. Respondents unanimously felt comfortable with the manners of discussion that this class demonstrated. However, the overall discourse style showed a difference. The participants used some of the interaction styles more often than others, i.e., exchanging information versus negotiation and argumentation. Instructors should intentionally encourage meaning negotiation in online discussions by engaging students in collaborative problem solving.

Introduction

Equal participation, the provision of equal opportunities for participants to contribute and to get feedback in conversations (Flanagin, Tiyaamornwong, O'Connor, & Seibold, 2002), in online learning environments is among the many factors spotlighted in recent research. In order to take advantage of these opportunities, participants must feel comfortable with the medium and the communicative style it allows. In particular, participants in text-based, computer-mediated communication (CMC) rely upon their verbal and linguistic behaviors to reveal information about opinions and attitudes (Adrianson, 2001).

Researchers (e.g., Howland, 2002; Markel, 1999; Moore, 2002) have attempted to determine equal participation in online learning and communication by examining participants' discourse (i.e., interaction) patterns according to gender differences. Although classroom discourse has been studied extensively (e.g., Edwards & Westgate, 1987), new forms of discourse occur in virtual settings (Harasim, 1990; Romiszowski & Mason, 1996). For instance, Markel (1999) found gender differences in discourse styles in an online virtual conference course for in-service teachers. She noted that female students used direct questions and responses to invite discussion; while male students made statements in challenging tones. As a result, males were more successful in receiving responses. The differences in discourse styles therefore contributed to the inequality of this group's online discussion participation. Arbaugh (2000)'s study revealed that men's level of participation in online course maintained stable and moderate levels until the end of the course. Meanwhile, women's participation levels were initially high, dropped to a moderate level, and increased at the end of the course. The results suggested that men placed more emphasis on the competitive aspects of the course as the term progressed, while women viewed the virtual classroom as an opportunity for collaboration and networking and valued the collaborative environment.

Flanagin et al. (2002) stated that "the likelihood, level, and nature of equalization that may occur in a CMC environment are not agreed upon or clear" (p.67). Their study discovered that men exhibited a greater desire to reveal personal information that reveals their social status, while women tended to "recognize and enjoy the social benefits afforded them through reduced social cues" (p.82). They also found that within the CMC environment, women may be more process-oriented than men and less concerned with group composition.

The Study

This review of literature suggests that men and women differ in discourse styles when interacting in the CMC environment. Building on this knowledge base through continued research will promote all learners' active participation in online learning, regardless of their gender. This study will also affect how instructors of the CMC environments conduct the collaborative learning experience. In this presentation, we will report findings from a case study that examines the discourse styles and participation of male and female students in an online graduate-level course. The foci questions of this qualitative case study include:

1. What are the factors (e.g., ethnicity, gender, knowledge base, cultural differences) affecting students' levels of participation in online discussions?
2. How does discourse style affect participation?

This introductory instructional design course focuses on the systematic design of products for education and training. The course engages students in both solo and teamwork tasks in completing several project deliverables. Students' development efforts culminate in a proposal for an instructional product and a report on prototype development and testing efforts. During the course, students interact with a cast of characters from a hypothetical educational design company, a firm that offers a wide range of educational products for corporate training markets and in all levels of public schools. Students work as contractors for this company.

Twenty-one students enrolled in this online course represent many parts of the United States and countries as far away as Hong Kong, Japan, Argentina, and Venezuela. Although the participants' professions are diverse, ranging from life skills teacher to course developer to eBusiness user and support analyst, they are all involved in training and education. Their age ranges from 28 to 45, with a mean of 37. Participants in this course communicated in English via a variety of synchronous or asynchronous tools, including email, class listserv, forum (Instructional Design Café), Live Webcast (an online broadcasting delivered by the instructor via RealProducer), live chat, and occasionally phone conversations. The class had a total of 9 males and 12 females. Their distribution in each of the two sessions is as follows: Session Feb. 7th (seven males and six females); Session Feb. 10 (one male and six females). One male student was absent from that week's discussions.

The researchers collected data primarily through observation of the live chat discussions and forum (an online café) postings. The course instructor provided a random sampling of two Webcast discussion transcripts. In order to accommodate students' schedules, the instructor held redundant Webcast twice a week. Both sessions addressed the same discussion topics and online activities, but involved different participants. The two transcripts represent a variety of discussions as well as interactive presentations and peer reviews.

An end-of-semester questionnaire was distributed to the students in May 2002, surveying their perceptions of the online experiences, self-rated participation levels, learning gains, and satisfaction with the course. The survey also elicited information about whether gender differences do exist in this online class, and whether the students' cultural backgrounds affect their manners of communication with others (e.g., disagreeing, negotiation).

Using Microsoft Word 2000, the researchers first used open coding (Strauss & Corbin, 1998) to individually code the sampled Webcast discussion transcripts. Open coding is a line-by-line analysis of discourse that identifies major concepts and groups them into different categories and subcategories according to their properties and dimensions. The researchers then synthesized the codes to develop a coding scheme, established interrater reliability (>80%), and used the scheme to systematically code all sampled data. Interactions in the transcripts were naturally divided by the individual's name. One discourse unit, an individual's typed input in this case, could be associated with multiple codes.

Synthesizing coding schemes from related research (Adrianson, 2001, Markel, 1999), the researchers generated the following coding categories to represent interaction styles:

1. Information: statements made to make a point or to clarify related issues.
2. Opinion: statements reflecting participant's personal views, an interpretation or inference from the discussion.
3. Suggestion: statements made to solve a specific problem.
4. Summary: recapture or reiteration of discussions.
5. Questioning-answering: questions asked and answers provided.
6. Negotiation: attempts in reaching consensus
7. Argumentation: attempts in imposing one's opinions on others.
8. Agreement and disagreement: upon topics of discussion.
9. Motive: motives implied when supporting a suggestion.
10. Metacommunication: statement referring to the process of communication itself, especially teamwork strategies.
11. Uncoded messages: reference to anything unrelated to the topics of discussion.

Findings

Results of Coding

The frequency (percentage) of substantial messages exchanged was used to assess participants' levels of participation. Greetings such as "hi, hello, howdy" and other courtesy words were excluded from counting. Coding analysis revealed that female participants' frequency of messages (57% of total exchanges) exceeds that of the male participants (43%). However, on-topic messages are closer in number, with messages by males at 48% and females at 52%. Males are more likely to discuss information (60%) while women are more likely to express opinions (85%) and ask/answer questions (79%).

A repeated measures ANOVA (Analysis of Variance) was used to test the statistical difference between gender and discourse style (indicated by the 11 coding categories). The results indicate that there is no statistically significant interaction between gender and discourse style ($F=1.453$, $df=1, 18$; $p=0.1908$, $a=0.05$). However, there is highly significant difference in the overall discourse styles indicated by the 11 categories ($p<0.0001$). That means the participants, regardless of their gender, used some of the interaction styles more often than others. A post-hoc analysis (Fisher's PLSD) reveals that there was a significantly higher amount of information exchange and suggestions provided. There were very few negotiations and no argumentation among the discussants.

Survey Results

The survey responses provided by the 10 respondents had high consensus (80%) and corroborate the researcher's observation and ANOVA test. In general, the respondents agreed that they were active in the online discussions, but could have participated more. They enjoyed the Webcasts, online discussions, and collaboration. The majority of the responses to the survey questions were positive (Agree, Strongly Agree) with no negative responses (Disagree, Strongly Disagree).

In particular, respondents unanimously felt comfortable with the manners of discussion (e.g. netiquette, respectfulness, etc.) that this class demonstrated. In addition, they all enjoyed teamwork, valued networking and collaboration. It seems that there were not any noticeable cultural differences in students' perceptions on ways of working--being collaborative or competitive. A predominant majority of the respondents (90%) did not notice any gender differences in the class discussions. Ninety percent of the respondents also perceived negotiation and debate as acceptable ways of communicating with classmates and the instructor. Only 80% felt comfortable expressing opinions that differed from the instructor's. Ninety percent of the respondents enjoyed teamwork and felt their inputs were valued by classmates.

Conclusions

This mini-case study did not reveal any significant differences in discourse styles according to gender in this graduate-level online class. It seems that the maturation and experiences of the students contributed more to the discourse styles than gender. However, the overall discourse style showed differences in that participants used some of the interaction styles more often than others, i.e., exchanging information versus negotiating. Although participants perceived negotiation as an acceptable way to communicate, they did not negotiate much in the discussions.

It has been noted in previous research that intensive negotiation and argumentation reflect the uninhibited effects of communicating in an Internet-based environment, which, as Walther (1996) argued, could facilitate a higher rate of information exchange and strengthen interpersonal and social relations. Social constructivist researchers (Derry, Gance, Gance, & Schlager, 2000; Mercer, 1995) have corroboratively discovered that negotiation and argumentation can contribute to a higher quality of knowledge construction. Future instructors should intentionally encourage meaning negotiation in online discussions, perhaps through engaging students in collaborative problem solving. In addition, balancing numbers of male and female students in a discussion session will be conductive to the establishment of a stronger social network.

Findings of this study were based on a small sample of data. In order to further identify discourse style and interaction patterns, the researchers will use Sequential Data analysis (Cuomo, 1994; McKean, Allen, and Hoffman, 2000) software (e.g., MacSHAPA) to systematically code more data samples. The software will represent the structure of codes in visual maps that indicates themes and patterns. The software can also count the frequencies of the codes, which can be analyzed through ANOVA tests for differences in the frequencies of certain discourse styles used by males and females. We will also examine the response rate (lengths, wait time, & frequencies of responses) between male and female to corroborate findings on their participations.

Syracuse University
Syracuse, NY 13244, USA
xwang09@syr.edu, spector@syr.edu

Abstract: A growing concern among those who implement online learning environments is how to effectively support and facilitate virtual group work. This paper describes four course projects in a distributed learning environment. The purpose of these efforts was to investigate the experience of students with virtual projects as a precursor to planning an online option for the capstone practicum course in the masters curriculum in Instructional Design, Development and Evaluation - a course that requires substantial collaborative project work with actual clients. The particular focus of this exploratory investigation was on how distributed learning environments influence group communication, cooperation and coordination. Benefits, problems and concerns inherent in virtual group work in online course settings will be discussed. Findings include the desire of virtual project team members to meet face-to-face initially and when difficulties were encountered.

Keywords: Distributed learning environment, Online course, Virtual project

Introduction

The growing complexity and dynamics of learning often require teamwork (Spector & Anderson, 2000). It is generally understood how to facilitate teamwork in face-to-face situations. At least there is often clear and immediate evidence when group processes breakdown in face-to-face settings, which allows for adjustments and corrective support. As information and communication technology increasingly is used in facilitating the learning process, virtual teamwork is more and more common. This situation requires additional investigation into how to effectively facilitate virtual projects in distributed learning environments.

The authors have participated in a distributed learning community as facilitators for several online courses. One of these online courses is an introductory survey course offered jointly by the Instructional Design, Development and Evaluation Program and the School of Information Studies at Syracuse University using WebCT as the course management platform. Students in this course study a variety of issues related to educational technology. Emphasis is equally balanced between knowledge about technologies and the use of technologies in educational settings. Technologies introduced include Web-based learning tools, assistive technologies for people with disabilities, multimedia and video-based systems, and so on. In addition to participating in online sessions, students work together in small teams with professional practitioners on a variety of technology-based projects in order to gain practical experience. The project requirement is to spend the equivalent of 45 hours working with clients on an educational technology project approved by the instructors. The capstone course in the IDD&E curriculum is more project-based than this introductory survey course. Before deciding whether there should be an online version of the capstone course, the faculty decided to first see how well virtual project teams would work in the introductory course when it was offered online. The results of four project teams are reported below.

The Projects

In the Spring semester of 2002, the online introductory course was offered online for the first time at Syracuse University. 12 graduate students from different programs and with different backgrounds worked on four projects: the Glossary Project; the Instructional Design Resources Project; the Daring Rural Education to Affect Meaningful Science (DREAMS) Project; and, the International Student Knowledge Management System Project.

The Glossary Project

Students were expected to plan and prototype an interactive, Web-based glossary of educational technology terms to serve as a prominent Web-based resource for professional instructional designers and educational technologists as well as for international students and for students transferring into educational technology from other disciplines. A graduate assistant football coach for SU, a non-matriculated full-time digital reference specialist for AskERIC and an assistant professor of mathematics at Utica College worked on this project. These students were all located in the central New York state area although not all in the same city. They had somewhat different work schedules as well.

The biggest challenge for this project turned out to be the involvement of students from two different courses rather than the fact that it was conducted in a virtual environment. This situation was imposed by the project sponsor and required students to use tools other than those embedded within the WebCT course environment. This requirement also created some dissonance in student roles within the project, since the student project leader was not in the introductory course. The requirements of the two courses were somewhat different in that the students in the more advanced course were not required to spend 45 hours with the client. This difference in course requirements sometimes created differing expectations among project team members. The major communication tool that evolved for this group was private email between each individual group member and the project leader. The project group members in the introductory class also used the email embedded in WebCT as well as a private discussion thread to facilitate their own collaboration. The fact that two course groups were involved made it difficult to assess how technologies available for communication, collaboration and coordination helped or hindered progress.

The difficulties that arose within the group due to the difference courses in which students were registered could have been expected to arise regardless of the virtual nature of the effort, although lack of face-to-face communication may have caused delays in resolving these difficulties. Nevertheless, there was substantial progress on the interactive, Web-based glossary and the project was considered as successful as projects conducted in a face-to-face team environment by the instructors.

The Instructional Design Resources Project

The project team was expected to plan and implement a Web-based repository of instructional design resources. The repository will provide relevant resources for instructional designers and people interested in understanding instructional design and relevant matters. A first year full-time masters student, a corporate trainer for the Hartford Insurance Company and a part-time masters student worked on this project. These students were all located in the central New York state area but had differing schedules.

Teleconferencing was employed as a major synchronous communication technology to facilitate group cooperation. Weekly teleconferencing was set up by one of the group members. During the teleconference, they exchanged information and shared work progress. Regular information was also exchanged using private emails with attachments. This group had more success in making progress more quickly than did other groups, and they did not experience any major difficulties. It is difficult to determine how much of this success is due to the communications technology selected although the group reported general satisfaction with this method.

Overall, the progress made by this group was judged well above average. It is likely that the mixed form of communications (including both Web-based methods as well as teleconferencing) and individual initiative exhibited by all three group members contributed to the success that this group experienced. It is noteworthy that this group devised its own forms of communications that went beyond those suggested by the instructors.

The DREAMS Project

This project team participated in the design and development of an innovative, Web-based, computerized learning environment designed to provide users motivational and enrichment experiences that facilitate the exploration of careers tied to agriculture and environmental sciences. An elementary Library Media Specialist, a high school social studies teacher, a graduate student in science education and a 7th grade English teacher worked on this project. While the team members were all located in the same general central New York vicinity, the client was located more than an hour's drive from the University.

The group met face-to-face at the initial phase and they reached agreement to communicate weekly in one of the chat rooms available in WebCT. The private discussion bulletin board was also actively used by this group. This project also had the most active assistance from the sponsor, which most probably accounts for much of their success. The variety and frequency of communications methods probably contributed to success as well. Overall, this group benefited from having a very involved project assistant who made sure that regular progress was occurring. While the end-user was located some distance from the campus, the sponsor's project assistant was available on campus and through local telephone service and quickly responded to problems as they arose.

The International Students Knowledge Management System Project

Project members engaged in planning and prototyping an interactive Website to support international students in the School of Education. The basic operating premise for this site was that international students can enrich learning and instruction for everyone as well as benefit from having a site dedicated to unique concerns of international students. A doctoral student in Teaching and Curriculum from Ghana and a masters student in the Information Management program from China worked on this project. Both of these students were located near campus and the project sponsor was on campus as well.

Asynchronous technology (e.g., email and discussion threads) was employed as a major communication mechanism. Students also met in person together several times and they also met with the client throughout the semester. The project sponsor for this effort provided only high level guidance and left the team members with an open and creative outlet for their ideas. The project involved the use of a Web-based knowledge management system that made virtual project work and progress potentially quite easy. The team made little use of this technology, however.

This team did manage to implement a prototype in the Web-based knowledge management system but it was not of sufficient quality to include in grant proposals, which was one of the overall goals. Since both team members were international students, they did manage to contribute much substance to the overall effort although the prototype was of marginal quality.

Findings

Collaboration on projects remains a challenge whether conducted face-to-face or via distance or distributed technology. Virtual collaboration can occur asynchronously (for example, through e-mail or postings on bulletin boards) or synchronously (for example, in teleconferences or real-time chat sessions). Many of the barriers to effective online collaboration are the same as for face-to-face collaborations. This became evident in the largest of the project team that had difficulty in settling on meaningful roles for the various project team members. Initial communication is a challenge for all project teams, whether working in virtual or face-to-face settings. Expectations play a key role in establishing effective communication. Those who cannot benefit from face-to-face contact, especially with key project personnel, naturally have more difficulty in developing reasonable expectations and workable project relationships. Some barriers to effective communication common to both environments may be exaggerated when people are collaborating without face-to-face interaction. As suggested by many researchers, an initial face-to-face meeting expedites trust, familiarity, and a willingness to collaborate; consequently, blended environments and a mixture of communications modalities may promote collaborative group work in many settings (Collison et al., 2000; Palloff & Pratt, 1999; Rosenberg, 2001; Simonsen et al., 2000). All but one of these groups managed to find effective ways to communicate early in the project, and all of the groups eventually managed to use a variety of communications modalities. The one group that had problems early on failed to include any provision for a face-to-face group meeting, which may account for the delays they had in getting the effort on track.

Sometimes technology itself causes a unique problem to on-line collaboration. The use of technology can obstruct communication, interaction and collaboration among group members, creating frustration among learners (Ragoonaden & Bordeleau, 2000). Examples of this include the lack of available access to the server during scheduled chat sessions, difficulty in locating the proper chat room, difficulty in uploading artifacts to a shared workspace, and so on. Unless participants are aware of the potential technical problems and how to go about resolving them, working out the problems can become a very frustrating process. As it happened with these four projects, the technical problems were not a real barrier, although the last group could have made better use of the Web-based knowledge management system that was the target for its prototype.

Just as instructors need to develop new skills for facilitating virtual communication, students also need to develop new skills to facilitate learning and working as members of a virtual learning community. Virtual projects require higher levels of interaction than do face-to-face projects, partly because face-to-face communication is both familiar and generally efficient. As a consequence, student participation and information processing in a virtual team environment generally feels more demanding to students than does participation and information processing in face-to-face settings. Based on this initial finding, teaching should help students develop reasonable expectation for virtual project work, making sure that students understand that some cognitive and behavioral adjustments in collaborative work habits are likely to be required. Finally, for many situations, a mixture of online and face-to-face communication and work strategies are likely to effective in many cases.

The Evolving International Role of a research university: An MIT Perspective

Janet Wasserstein
Communications and Development Officer
Center for Advanced Educational Services (CAES)
Massachusetts Institute of Technology
United States
JanetW@mit.edu

Co-author: Professor Richard C. Larson, Director, CAES

Abstract: MIT's Center for Advanced Educational Services is taking major strides in crossing the digital divide through innovative web-course development and strategic e-learning partnerships. This paper will highlight "The Learning International Network Consortium" LINC, a global initiative to empower organizations within developing countries to design, create and operate top quality higher-education e-learning systems. Also highlighted will be the MIT-African Virtual University partnership and the creation of the first two in a series of free interactive web-based courses for healthcare professionals.

Introduction

The role of a research university today, compared to fifty years ago, now needs to be aware of the global picture and interconnectedness. If tertiary education leads to greater understanding internationally and empowers students, what role should a research university play? At MIT, several programs are currently underway that address this question.

MIT offers some distance learning programs but does not offer degrees solely through distance learning.[i] There are other universities that concentrate on that area. MIT is interested in researching new educational technology such as interactive online tutors (e.g. PIVoT[ii]), and initiatives such as the Open Knowledge Initiative and Stellar[iii]. MIT is also looking at new pedagogies that are goal-oriented, non-linear and experimental and new ways of collaborative learning such as the Technology Enabled Active Learning project (TEAL[iv]).

MIT employs many different models for distance learning or technology-enabled education as part of teaching tools that have global dimensions. MIT provides outstanding content by its faculty and innovative research in ways of teaching and learning.

I. MIT models of global learning initiatives

Publishing Model

The latest project that has received much publicity is OpenCourseWare. This is a project to put MIT course materials up on the web free and open to the public. This is not distance learning, however, as no interaction occurs between teacher and learner, but it is an invaluable resource for students and teachers across the globe. "The idea behind MIT OpenCourseWare (MIT OCW) is to make MIT course materials that are used in the teaching of almost all undergraduate and graduate subjects available on the web, free of charge, to any user anywhere in the world. MIT OCW will radically alter technology-enhanced education at MIT, and will serve as a model for university dissemination of knowledge in the Internet age. Such a venture will continue the tradition at MIT and in American higher education of open dissemination of educational materials, philosophy, and modes of thought, and will help lead to fundamental changes in the way colleges and universities engage the web as a vehicle for education. MIT OpenCourseWare will provide the content of, but is not a substitute for, an MIT education. The most fundamental cornerstone of the learning process at MIT is the interaction between faculty and students in the classroom, and amongst students themselves on campus."[v]

MIT Learning Networks

Learning networks are used in many different programs at MIT and are defined as spatially dispersed communities connected together by a variety of communication technologies where everyone is a learner and a teacher, and many opportunities exist for collaborative research[vi]. Examples of these partnerships include the Singapore MIT Alliance (SMA) and the Cambridge MIT Institute (CMI).

Using asynchronous and synchronous technology as well as on-campus immersion, the Singapore MIT alliance is MIT's largest distance learning project and is an innovative engineering education and research collaboration between the National University of Singapore, Nanyang Technological University and MIT (http://web.mit.edu/sma).

This model can best be described as follows: "At MIT, we are using the broader bandwidth Internet2 to deliver five new professional masters degree programs to students on our Cambridge-based campus and to students 12 time zones away in Singapore. But beyond formalized distance learning, SMA involves collaborative faculty research, student exchanges and a wide variety of activities that result in a type of global campus spanning the Pacific".[vii]

II. Current MIT initiatives from CAES to reach global audiences

MIT is a community of over 10,000 graduate and undergraduate students. In 2001-2002, MIT's international student population comprised 8% of undergraduates and 38% of graduate students from 109 different countries. MIT students need to be prepared to enter a global economy and MIT is connected to research institutions all over the world. The MIT International Science and Technology Initiatives (MISTI), for example, have cultural exchange and global programs that have reached thousands of students worldwide. This paper can only touch on a few of the current and planned initiatives from MIT and the focus of this paper will be on the initiatives of CAES – one of MIT's main centers of technology enabled education and distance learning – that collaborates with other MIT schools and departments.

Using some of the models described above, over the last year, CAES has increasingly focused on disseminating its knowledge globally particularly to developing countries through distance learning. The reasons for this outreach are several: the world is transitioning from an economy based on manufacturing and natural resources to one that is more focused on information and knowledge; developing countries have become very active in web based distance learning (e.g. Pakistan, Uzbekistan, Tunisia, Algeria, Jordan, South Africa, Tanzania, Iran); and technology can increase access to larger audiences.

The following three projects are the latest initiatives of CAES (http://www-caes.mit.edu/index.html) :

MIT World

One of the most successful projects of CAES, ***MIT World*** follows a similar model of OpenCourseWare to bring content to global audiences. Although there is no interactivity, intellectual content from MIT can now be seen from Mali to Massachusetts – or indeed by anyone with a computer, Internet access and RealVideo player. ***MIT World*** is a free, open, video streaming web site that currently provides on-demand video of significant public events at MIT (http://web.mit.edu/mitworld). It is the venue for the MIT community, alumni, and the public at large to have access to video taped events at MIT. Content includes: 2001 Nobel Prize in Physics Lecture by Wolfgang Ketterle on "The Coldest Matter in the Universe" and Nobel Laureates David Baltimore, John Hume, Charles Townes, Franco Modigliani, Paul A. Samuelson, and Robert M. Solow. Lectures cover a broad range of subjects including the arts, economics, politics, computer science and management.

African Virtual University

More than 190 students from eight sub-Saharan African countries (Ethiopia, Ghana, Kenya, Mozambique, Rwanda, Tanzania, Uganda and Zimbabwe) participated in an MIT course without leaving their continent, through a partnership between CAES and the African Virtual University. Using asynchronous and synchronous methods, CAES offered a six-week curriculum loosely based on MIT's Introduction to Computers and Engineering Problem

Solving (1.00), which teaches the Java programming language. The resulting course, Java Revolution, was uniformly distributed regardless of equipment and bandwidth. Thirteen learning centers participated, and we expect to enroll more African students in MIT courses in the future. Java Revolution featured videotaped lectures via satellite, a web site for course materials, e-mail moderated by teaching assistants, and two live videoconferences.

Two Interactive Web-based courses

With financial support from Pfizer, CAES and the Harvard MIT Division of Health Sciences and Technology have created the first two in a series of free, interactive web-based courses for healthcare professionals: "Good Practices in Clinical Research" in Spanish and English primarily for physicians in Latin America; and Fungal Infections: Virtual Grand Rounds as a response to a disease that is endemic in many developing countries (http://figrandrounds.org/fi/index.html)

Learning International Network Consortium (LINC)

The Director of CAES, Professor Richard Larson, is the Principal Investigator for a new project that we hope will receive funding in the fall of 2002: the Learning International Network Consortium (LINC). Using the train-the-trainer model, CAES plans to bring world-class educational opportunities through distance learning to those who have not had access to quality education.

LINC is an MIT-managed initiative aimed at the creation of a global community of scholars and practitioners who seek to use modern computer and telecommunications technologies to increase the reach and impact of higher education especially in developing countries. LINC will be a voluntary e-learning network and resource center connecting and building upon individual national and international efforts currently underway. Using e-learning and related technologies, LINC will empower educators working in their own country to bring higher education to a wider population. Students of current 'brick and mortar' university programs will join faculty members and others in collaborative research and development to help create positive change. Educational content will focus primarily in the areas of science, engineering, management, humanities, arts and social sciences.

The key purposes are to empower organizations within countries, especially developing countries, to design, create and operate top quality higher-education e-learning systems; to share educational materials, exercises and courses for the mutual benefit of learners across all participating countries; and to become the top tier community of scholars and practitioners whose focus is technology-leveraged higher education internationally.

The Consortium will be assembled from diverse efforts now operating within many developing countries, utilizing best pedagogical practices whenever possible. LINC will bring world-class educational opportunities to those who do not have access to quality education by partnering with and training teachers in developing countries, who will then work within their own country to increase outreach. At the same time, those in developed countries will have the opportunity to learn about different cultures through the educational networks established by LINC. Members of LINC will be colleges and universities, not-for-profit organizations, foundations, private corporations and selected governmental agencies. Expanding and sustaining e-learning efforts throughout the developing world will be the primary focus of LINC. The reasons behind the initiative include:

- Developing countries are likely to fall further behind the developed world in terms of economic growth and prosperity, without some feasible system for educating their youth. This in turn could lead to larger inequities in the distribution of the wealth of nations and potentially act as a destabilizing factor in world events.
- Establishing a two-way exchange of content between the developing regions and the developed world will enhance mutual understanding and provide a rich source for cultural studies.

Some of the specific goals and services of LINC are as to:

- Host an annual international conference on "e-Learning in the Developing World" that would share "lessons learned", present best practices in e-learning and project plans for future years.
- Design the management and membership protocols and processes of LINC, leading to a sustainable and readily growing organization.
- Create and distribute a variety of educational content both intra-country and across national boundaries.

- Using the train-the-trainer model, design systems and utilize technology to leverage scarce teaching resources within and between countries to reach a maximum number of learners. LINC would provide resources that would focus on training those who in turn would train others in the technology, pedagogy and business of e-learning.
- Create and maintain an easy-to-use web platform for communication among LINC participants and for assisting in the hosting of educational materials.
- Host a complete searchable repository of international e-learning projects and activities that are underway, so participants can identify potential partnerships and other synergies.
- Establish a global network of learners to advance the sharing of skills and raise economic standard of living.
- Raise the educational level of population globally.
- Undertake collaborative research and development, involving faculty and students at existing institutions of higher education, to further this effort.

Conclusion

CAES plans to leverage its educational technology projects and direct much of its attention globally to developing countries.[viii] Distance learning and technology-enabled education will allow increased access to tertiary education – a scarce resource in many countries.

Abstract: We have developed a multi-lingual Web-Based E-mail client system by JavaServlet technologies. The system, which is named "Servlet WebMailer", can handle character sets of various languages. When a user browses a mail message using the system, the system recognizes a character set of the message, at first. The system converts the message into Unicode, and displays the message. When a user composes a new message, the user can determine a character set to write the message. The system recognizes the character set, the system converts the message from Unicode to an appropriate character set. We release this system as free software.

Introduction

Web-Based systems are important technologies in recent years. Various systems are implemented in the world. Web-Based E-mail system is one of a typical example of the Web-Based systems. There are many sites operating Web-Based E-Mail services such as "the Hotmail (provided by Microsoft Corporation)"(Microsoft Corporation, 2002). However, every system can handle only one language except English. Because of above reason, users can use his/her native language and English, but can not use other languages. It course problems. For example, Japanese people have to exchange E-mails with Korean people by English, even if the Japanese can read and write Korean.

We have developed a multi-lingual Web-Based Email client named "Servlet WebMailer" using JavaServlet technologies (Sun Microsystems, 2002). The system can handle character sets of various languages at not only browsing messages but also composing messages. In this paper, we describe an outline of the system, how to use the system and implementation of the system.

The Outline

Diagram of the System

The "Servlet WebMailer" is a Web-Based Email client. Fig. 1 shows a diagram of the system. The system works on WWW server. The users use the system via Web browser. Off course, SMTP server and POP or IMA4 server are needed.

Characteristic Features

The system has following features as E-mail client.

(1) Support POP3/IMAP4/SMTP protocols
(2) Support APOP authentication
(3) Address book and signature for users
(4) Text and HTML mail browsing
(5) File attaching/Retrieving files from mail

Further more, the system is multi-lingual. A user can use various languages not only for browsing messages but also for composing messages.

How to use the system

Login and message browsing

The system has similar styles of usage to the other E-mail systems. So that, many people may use the WebMailer without any trouble.

At first, the user starts Web browser and accesses the system. The first window is for login dialog (Fig. 2). The user has to input his/her username and password of the mail server, then click the "login" button to enter the system. The user can select protocols for E-mail message retrieving by which POP3 and IMAP4. After the login procedure, the main window is appeared (Fig. 3). This window has three frames. List of messages are shown in the upper frame. A message is shown in the middle frame. The bottom frame is for the commands to operate the system. The system shows a list of all received messages in the upper frame. A string in the Subject: field works as a link to the message. When the user clicks the link, the message appears in the middle frame (Fig. 3). In this example, the user is browsing a message written by Korean. This figure shows the system is developed as multi-lingual systems.

Composing a new message

When the user composes a new message, he/she should to click the "compose" command. Then the new browser executes and appears the composing window (Fig. 4). The user should fill To:, Cc:, Bcc:, Subject: and message to appropriate fields. After complete message, the user clicks the "send" button. Then the message is sent. The user can attach files into the message up to three files. The user inputs file names into the attachment1, 2 and 3 fields. The files are encoded as MIME multipart messages (N. Freed and N. Borenstein, 1996A, 1996B) automatically. To select the character set from "character set" select-box, the user can determine a character set of the message. The system knows the character set, the system encodes the message into an appropriate character set during message transfer procedure.

Other functions and Logout

The system has other function such as address book, signature, mailbox operation and so on. The user can use these functions via main window shown in Fig .3. When the user has done everything, click "logout" command to logout.

The Implementations

The JavaServlet and the Unicode

The system is implemented by JavaServlet. The JavaServlet is a programming language for server-side Web-Based systems. The JavaServlete can handle "Unicode" as internal character code. Unicode provides a unique number for every character, no matter what the language (Unicode, Inc., 2002). The JavaServlet has character conversion functions between Unicode and other characters. We apply this feature into the system to develop multi-lingual systems. Each E-mail message has own character set. When the system browses the message, the system converts the character set into Unicode. When the system sending a message, the system converts Unicode message into the character set. We will describe following three multi-lingual functions in the following sub-sections.

(1) Characters in the interface
(2) Message browsing
(3) Message composing

Characters in the interface

Mentioned above, the internal character set of the system is Unicode. If the "internationalized interface" button is checked at the login, the system displays every character by the "UTF-8" (X/Open Company Ltd.). The UTF-8 enables mixed-language interface. For example, Japanese and Korean display simultaneously in Fig. 3.

Message browsing

When a user browses a mail message, the system recognizes a character set of the message according to find "charset" parameter in mail header fields, at first. The charset parameter indicates what character set is used in the message. The system knows the character set, then the system converts the message into Unicode message. The charset filed is defined in RFC2045 as internet standards (N. Freed and N. Borenstein, 1996A). The system supports almost charsets.

Message composing

When a user composes a new message (Fig. 4), the user can determine a character set to write the message to select the character set from the character set select-box. The system knows the character set, the system converts the message from the Unicode to the character set during message sending procedure.

Conclusion

We have developed a multi-lingual Web-Based Email client named "Servlet WebMailer" using JavaServlet technologies. The system can handle character sets of various languages at not only browsing messages but also composing messages. The system is released as free software. If you evaluate the system, you can get it from following URL.

A Knowledge Handling Model in Educational Activity

Toyohide Watanabe
Department of Information Engineering,
Graduate School of Engineering, Nagoya University
Furo-cho, Chikusa-ku, Nagoya 464-8603, Japan
Phone: +81-52-789-4409, Fax: +81-52-789-3808
E-Mail: *watanabe @ nuie.nagoya-u.ac.jp*

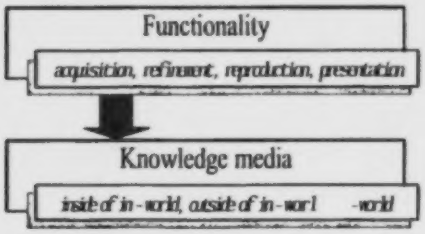
Abstract *Until today, many efforts about the educational support system have been reported, but the effects are not always proven sufficiently. As a powerful educational support system, it is necessary to investigate what functions are required, how to provide the functions, etc. with respect to the fundamental viewpoint for the educational activity of handling knowledge. In this paper, we address a framework of handling knowledge on the basis of educational activity of person. Our objective is to adjust facilities for handling knowledge explicitly so as to look upon our educational activity as a system-supplied mechanism. As a result, we could define a framework for handling knowledge by introducing four operational functions and three knowledge states.*

Introduction

The computer-supported educational systems have been developed as one objective to apply computer powers to various education domains and promote the abilities and activities of learners. However, the traditionally-developed/investigated educational systems are not always designed to supply the knowledge handling process integrated constructively among various education domains for users, but provide only question-answering facilities for exercises and/or explanations or tutoring facilities for individual instructions. When we look upon our educational activities as the knowledge management, it is important to design and implement the cooperative and successive mechanism among individual phases of knowledge management[1].

I.Nonaka, et al. has proposed SECI model which promotes human knowledge management in the organization systematically[2,3]. SECI model encourages four kinds of knowledge-oriented activities under the transition mechanism between two different types of knowledge. Four kinds of knowledge-oriented activities are exclusively classified into the socialization, externalization, combination and internalization SECI model can successfully explain the transition process of knowledge management for individuals in the organization, but is not always adaptable to specify the personal activity for knowledge management or the environment for personal knowledge handling[4-6]. On the other hand, SECI model is not sufficient to specify personal activity without any predefined procedural framework, and is in short of the representative functionality for flexible and intentional activities, which has not been yet prepared in the organization.

In this paper, we discuss first individual functions for handling knowledge and then knowledge representation domains to be manipulated by functional facilities. Additionally, we address the operational relationship between functional facilities and knowledge representation domains. Our idea is to integrate functional facilities with knowledge representation domains correspondingly so as to make the meanings of individual functions clear on the knowledge representation domains. From a viewpoint of this discussion, we divide functional facilities into four different classes, and also partition knowledge domains into three independent sets.



Functionality
acquisition, refinement, reproduction, presentation
Knowledge media

Figure 1: Framework of knowledge handling

Framework

Figure 1 shows our framework of handling knowledge conceptually. Our framework is defined by two layers: functionality, and knowledge media. Also, the framework

BEST COPY AVAILABLE

becomes effective when the facilities can be assigned to the knowledge media.

The functionality defines operations for handling knowledge, and is illustrated as knowledge manipulation facilities, such as acquisition, refinement, reproduction and presentation. These facilities may be implemented as role-dependent features and/or be sharable among person roles, associated with different educational environments. At least, seamless transition among these facilities must be powerfully supplied so as to make our educational activity effectual. On the other hand, the knowledge media indicates the information store assigned to subjective person of educational activity, and keeps the consistency in cooperation with knowledge handling facilities. So, the knowledge media accumulates the final/intermediate results. In this case, the knowledge media is not only human brain, but also is regarded as his/her own educational field and its associated tools/means. This modeling viewpoint is very important to construct our educational environment of personal activity as an operationally system-supported mechanism, but not as a mental model.

Functionality and Knowledge Media

We assume that the knowledge is composed of collections of related frames or their networks in order to make the meaningful roles of knowledge handling functions clear. Of course, even if this assumption was incorrect, the incorrect understanding for knowledge structure does not give any heavy drawbacks to us. This is because it is important to investigate different kinds of knowledge handling functions in the educational environment from a viewpoint of personal activity.

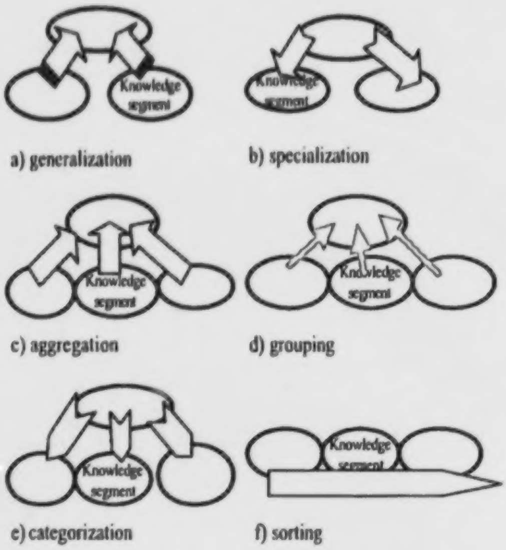
The knowledge handling is categorized into four classes: acquisition, refinement, reproduction and presentation.

1) Acquisition: the knowledge is transferred from *external-world* to *internal-world* in order to generate, add and re-structure newly nodes or edges for existing ones;

2) Refinement: the existing knowledge is modified for attributed values of nodes and/or edges, and can be reorganized in accordance with the relationships among individual nodes and/or edges. When this reorganization can be analytically categorized from a constructive point of view, the typical refinement functions are regarded as the generalization, specialization, aggregation, grouping, categorization, sorting, etc., as illustrated in Figure 2;

3) Reproduction: all these functions such as expansion, creation and discovery generate new knowledge from currently predefined one. Figure 3 illustrates the difference among them conceptually, using the properties and domains of knowledge segments. The domain is loosely defined as the field, related to a main subject. While, the property is roughly corresponded to the attached procedure, fundamental mechanism or etc;

4) Presentation: this function moves the knowledge from *internal-world* to *external-world* with a view to arranging its own content or its relationship among related ones systematically.



a) generalization b) specialization
c) aggregation d) grouping
e) categorization f) sorting

Figure 2: Refinement functions

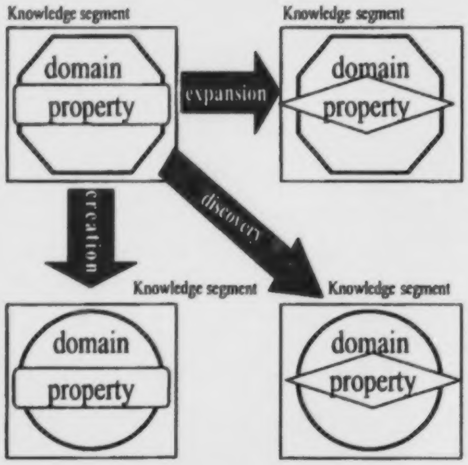


Figure 3: Reproduction functions

Figure 4 shows the functionality on three interaction spaces: ***inside of in-world***, ***outside of in-world***, and ***out-world***. ***Inside*** is our brain in itself; and ***outside*** is an interaction activity space for our supplementary or complementary tools/means such as notebooks, textbooks, memos, etc. which can be prepared as extended memories for our own brains by ourselves. Therefore, in Figure 4 computer-supported facilities can explicitly be implemented as the functions related to ***outside***. ***Outside of in-world*** enables to clarify knowledge objects to be directly manipulated. The circles in each space are typical states for individual spaces and the functional indicate the transitions among these states.

Internalization

System Architecture for Knowledge Handling

Table 1 represents the transition relationships among three states with respect to the operations for handling knowledge. Of course, Table 1 is derived directly from Figure 4. In comparison with Figure 4, Table 1 makes the relationship among the mutual operations for handling knowledge clear. From a viewpoint of this knowledge handling between our educational activity and environment, the framework in Table 1 supports the externalization and internalization between *in-world* and *out-world*, associated with education process of our activity. The externalization is an action to make our knowledge structure and content (or representation) explicit for others. In Table 1 ***refinement*** (inside : outside), ***presentation*** (outside : out-world) and ***presentation*** (inside : out-world) are typically regarded as the externalization: ***refinement*** (inside : outside) is the externalization for self-confidence; and two ***presentation***'s are so for other persons. Here, we can define the mutual transition relationship as follows:

[Ex.1] ***presentation*** **(inside:out-world) =** ***refinement*** **(inside:outside) *** ***presentation*** **(outside:out-world)**

Figure 5: Interpretation of our knowledge handling model

Namely, "*presentation* mapped directly from inside to out-world" is effectually replaced by a sequence of "*refinement* from inside to outside" and "*presentation* from outside to out-world". These functions are located to the right-upper side, as denoted by three hatched columns.

While, the internalization is an action to improve or re-structure knowledge definitely. In Table 1, *reproduction* (outside : inside), *acquisition* (out-world : outside) and *acquisition* (out-world : inside) may be looked upon as the internalization. In particular, *reproduction* (outside : inside) is self-improvement, like the knowledge expansion. Two *acquisition*'s are the knowledge transfer with/without layout structures of knowledge forms. The relationship among these functions is specified as follows:

[Ex.2] ***acquisition* (outside:inside) = *acquisition* (out-world:outside) * *reproduction* (outside:inside)**

Namely, "*acquisition* mapped directly from out-world to inside" is successfully replaced by a sequence of "*acquisition* from out-world to outside" and "*reproduction* from outside to inside". These functions are located to the left-lower side, as denoted by three hatched columns.

Next, we consider the meaning of personal activity in Table 1. Our functionality model in Figure 5 and relationship diagram among functions in Table 1 indicate transitions for knowledge handling of personal activity. Here, we introduce the concepts "Socialization" and "Combination" which were proposed by I.Nonaka in SECI model, and adapt them to Table 1 under the assumption that the behavior from *inside* to *inside* is "Socialization" and that from *outside* to *outside* is "Combination". As for "Socialization" this is because the transition from *inside* to *inside* in not explicitly observed for us and also the knowledge reorganizations or improvements are tacit forms/contents. Similarly, concerning to "Combination" the transition from *outside* to *outside* as the refinement is so interpretative to transform or re-arrange knowledge in better representation forms/contents. Of course, the concepts "Externalization" and "Internalization" are already discussed as above. As a result, we can get Figure 5, derived from Table 1. Also, we depict SECI model in Figure 6 in accordance with the similar dimensions. In comparison with Figure 5 and Figure 6, our model includes SECI model and makes the expressive relationship among different activities stronger. Of course, in Figure 5 the relationship for each field is the transition between knowledge handling phases, while in Figure 6 the relationship for each field is the transition between knowledge forms. Thus, these viewpoints are not always consistent: our model should be designed to be adaptable to the personal activity for knowledge handling; and SECI model is intended so as to explain the knowledge management in the organization. In Figure 5, we observe flexible transition among individual activities but not a simply spiral transition.

Conclusion

In this paper, we addressed the functionality and knowledge media for handling knowledge, and also made it clear that the functionality could be defined well on three categorized knowledge media. We defined four different operations for functionality such as acquisition, refinement, reproduction and presentation, and also three different knowledge media, such as inside of internal world, outside of internal world and external world. Under the relationships between four knowledge handling functions and three knowledge media, our knowledge handling is systematically implemented as the computer-assisted mechanism. As for our future work, we must investigate practical procedural functions on the outside with respect to current framework in order to promote the user interaction and activity progressively.

Missouri/Taiwan High Tech-High Touch Excursion

John Wedman, Ph.D. and Laura Diggs, Ph.D.

University of Missouri-Columbia

Was John Naisbitt, author of Megatrends, correct two decades ago when he predicted that, the more technology is introduced into society, the more people will aggregate? Since fall 2001, the University of Missouri has facilitated a high-tech partnership involving high school students and teachers in Missouri and Taiwan. In summer 2002, students from Taiwan will visit Missouri to collaborate in lessons and activities facilitated through extended partnerships with Boeing Corporation and the St. Louis Science Center.

This venture will take Missouri and Taiwanese students on high-touch excursions through a flight museum, planetarium exhibits, astronaut wind tunnels, an aircraft assembly line, an avionic electronics lab, and a simulated space station. Throughout the excursions, the students will capture digital artifacts for inclusion in a documentary of the visit. Designed by students during the Missouri event, the documentary will be created and displayed during ThinkQuest. Using various software development applications and large databases (e.g., satellite photographs, maps, etc), Missouri students in Seattle will work directly with students in Taiwan using Internet Video and Shadow netWorkspace (SNS is an open source CSCL environment), the goal being to assemble a multi-media, multi-lingual digital documentary of the recently completed visit. Event observers will have the opportunity to see the "real-time" work of these students and to play an active role in finalizing the documentary. Decide for yourself…was Naisbitt correct?

This paper describes in depth one project that the University of Missouri-Columbia College of Education (MU CoE) has implemented as part of a globalization initiative. There are currently 4 schools in Taipei, Taiwan that are connected with K-12 schools in Missouri as well as MU faculty and pre-service teachers. This year, the MU CoE sent three faculty and staff members to Taipei to develop and implement a literature-based English curriculum for students to share with their American counterparts. The goals of this globalization initiative are a critical 3-part model that is a unique experience that currently does not exist. This experience evolves around information and learning, enabling technology, and global connections. This 3-part model is based on: 1) connecting K12 schools in Taipei, 2) with K12 schools in Missouri, and 3) MU CoE Literacy faculty. The connection is provided through utilizing Internet2 and video conferencing equipment.

The process of this globalization initiative focuses on individual school needs, but all involve utilizing technology to allow students to have email as well as face-to-face conversations to practice online communication, establish friendships with students of other cultures, exchange cultural information, and develop and understanding and tolerance for other cultures. Students from both cultures benefit from the opportunity to improve their English language (written and verbal) skills as well as identifying the benefits and limitations of online communications.

Current projects where partners include schools in Taipei working with Missouri schools include two elementary schools, one K-9 school, and one senior high school. Projects include development of web sites for descriptions and pictures of participating teacher and students, the school and surrounding community, special events and holidays, as well as information on foods and day-to-day life for students their age. Schools have participated in paired reading of English children's literature books and had face-to-face video conversations around the books. Several schools are participating in science projects together where they collect samples of vegetation, water, and wild life to compare and contrast on the web site with their partner school. With the time difference between Taipei and Missouri being a complicating factor, partners are sharing information through threaded discussions and emails as well.

The impact of this globalization initiative has proven to be beneficial to the Taiwanese students having authentic conversations with native speaking English speaking students their own age and improving their English writing and oral skills. The Missouri students have discovered a new cultural appreciation as well as developing friendships. The MU CoE faculty and pre-service teachers have acted as cyber-tutors to help in the writing process as well as professional development for the Taiwanese teachers.

A Mobile Augmented Reality Environment for Collaborative Learning and Training

Reiner Wichert
ZGDV, Computer Graphics Center
Mobile Information Visualization
Darmstadt, Germany
reiner.wichert@zgdv.de

Abstract: The following work focuses on the requirements for a Collaborative Augmented Reality System with the usage of Internet technologies to create new possibilities for collaborative teaching. In most learning environments, learning is imparted through seeing and hearing. In this paper, Collaborative AR Discussion and personal experience are also integrated in order to achieve a quicker transmission of study material and an increase in memory efficiency. We have analyzed the scenarios occur most frequently in service and maintenance and also the literature of Tele-Teaching. The needed requirements were derived and as a result integrated in a test system. This collaborative game simulates a web-based training and teaching environment in Collaborative AR as a new approach for teachers and trainees and describes scenarios and research perspectives for distance education and training at the same location. The game was used as a testbed to clarify the problems associated with AR and Collaborative Learning.

Introduction

Through the integration of Multimedia, study material can be transmitted much faster. In 1965, William Glasser described what influences a student's ability to retain information and ideas in his book Control Therapy in the Classroom. Respective to this thesis, people remember 10% of what they read, 20% of what they hear, 30% of what they see, 50% of what they see and hear, 70% of what they discuss with others, 80% of what they personally experience and 95% of what they teach others (Glasser 65). With Collaborative AR, learners communicate directly with each other in a face-to-face communication, but also interact with remote learners located in other learning rooms. According to Glasser, and as it relates to the interactive aspect in the learning environment of a Collaborative AR, people can remember information in a very efficient way, because users can discuss and have experiences by interacting with the augmented world in the collaborative learning and training environment.

Tele-presence as a multimedia aspect and the access to worldwide distributed information enable a new way of teaching and learning. By combining learning and multimedia, a couple of net-based teaching and training systems have already been realized. By *Tele-Teaching*, we mean the distribution of knowledge in a synchronous Online Scenario or net of computers, in which the teachers and students work simultaneously. By *Tele-Training*, we mean the provision of study materials on network servers. These materials are retrieved by students asynchronously. Tele-Teaching is usually associated with university study, while Tele-Training is more suited for further professional training in a cooperate setting (Effelsberg).

Augmented Reality (AR) has become an important part of computer graphics. "Unlike Virtual Reality where the physical world is completely replaced with synthetic environments, in Augmented Reality environments, 3D computer graphics objects are mixed with physical objects to become part of the real world" Billinghurst says (Billinghurst 00). Computer Supported Cooperative Work (CSCW) has also been expanded as an identifiable interdisciplinary research field. According to Wilson, CSCW is a generic term, which combines the understanding of the way people work in groups with the enabling technologies of computer networking, and associated hardware, software, services and techniques (Rodden 91). By combining CSCW with Augmented Reality, a new collaboration - Collaborative AR - became possible. Collaborative AR is defined by Reitmayr and Schmalstieg, where co-located users can experience a shared space that is filled with real and virtual objects (Reitmayr 01). The use of CSCW technologies in combination with Tele-Teaching and Tele-Training opened a new application area known as Computer Supported Cooperative Learning (CSCL) (McCONNEL 94). But it is a new idea to take CSCL into Collaborative AR. With Collaborative AR, group discussions are possible, where each user can interact and attain personal experience. In reference to Glasser, it is the best way to achieve a quicker transmission of study materials and an increase in memory efficiency.

Findings

Today, the ability to communicate with almost anyone, to exchange knowledge, solve problems, and learn new things via computer networks is widespread. We know that we learn most effectively if we learn together with others in groups. The Internet allows cooperative learning independent of time and place (IPSI).

Almost all of the existing e-learning systems do not support AR. So, one of the advantages of the component-based System will be to support individual users in their simultaneous interaction with augmented objects by using Collaborative AR while exchanging knowledge.

To specify the requirements for a cooperative AR learning environment, the scenarios that occur most frequently in service and maintenance have been analyzed and two standard situations were identified:

1. cooperative interaction in a master / trainee scenario at the same place with e.g. skilled workers and a teacher having different views to the augmented world, standing and discussing in front of a machine;
2. direct interaction with a remote expert using AR Technologies like interactive video and having the same view as the skilled worker. The expert can interact with the skilled worker and offer support.

From these standard situations we have derived the following needed technical and interactive requirements. A collaborative AR system should give support and assistance to a learning group in their common work. Multiple users can be at the same place, at the same time, interacting together directly in the augmented world. Furthermore, group discussions are supported within the field of Augmented Reality. A common central view is established for each participant in order to get a defined understanding of the problem and to meet the requirements for this specific problem. Another aspect of teaching and collaboration is that an AR system has to provide remote support with the help of Augmented Reality over great distances. However, with a mobile aspect, the system would give multiple users access to information and help at any given time. It should clarify technical aspects, such as how to distribute the functionality in a learning collaboration and which methods can be used to get visual or haptic feedback. To meet the requirement of interaction by a collaborative group, a game could be implemented using the Collaborative AR Prototype System with the advantage of 3D group interaction and individual views for multiple users co-operating at the same place or with a connection over the Internet to remote users. As a result, a 3D Tetris clone was implemented as a testbed for different scenarios.

The Tetris game poses a good possibility for realizing the requirements of a collaborative AR learning environment, because it can be played at the same place or from a remote location. It is possible to login dynamically and share the AR Tetris game with other participants. It simulates e.g. the collaboration of skilled production workers and the connection of technicians to a remote expert for support over the Internet. Exploring this research topic within a game presents a significant challenge.

The Tetris game is split in the functionality realized by the Tetris Application and the visualization by the rendering component of the AR system. Both are embedded inside the web page, which displays points, the next piece, and the augmented view of the game (Fig. 1). The Tetris application can be started by any player and other users can login dynamically and share the AR Tetris with these participants. To realize this aspect, the status of the game is transmitted into the collaboration component. The first player who starts the game has the role of the master. The other players do not start another game, but get this status at the beginning of their session and initialize their game with these settings. If a player rotates a piece, the orientation of the actual piece will be set into the system. If a translation is done, the new position of the center of the piece is set in the system. A video server captures the picture of the camera and provides it to the rendering component and to the marker-based tracking system. A component was needed to handle the communication between the main components of the base AR system and to notify other components or other clients co-operating together when values are changing.

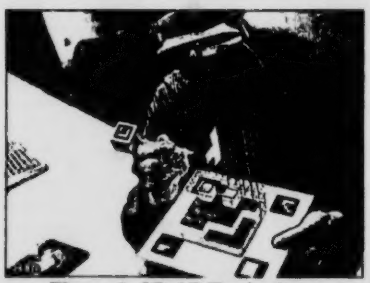

Figure 1: 3D AR Tetris clone

In the case of the collaborative learning environment, the values to transmit are the orientation of the scene, the names of the virtual objects used and also the actions like translations or rotations. The values are present on both the client and server side and are compared by way of a Push Mechanism. The Push Mechanism has been conceived to forward a notification to the clients immediately after an event occurs. Both client- and server-sided components can be informed via notification by the Event Mechanism. Another component is responsible for controlling the collaboration. If two users are changing a value at the same time, this component has to recognize and regulate the collision detection and the common concurrent interaction.

Scenarios

This Collaborative AR System can be used in a wide range of educational, e.g. in the field of commerce, to help users in their homes by way of a furniture company consultant, or in the industrial field, to support skilled workers standing in front of a machine by enlisting an expert. By using Collaborative AR to transmit study materials, a Cooperation at the same place is enabled by transmission of the scene, the actions and the orientation of the virtual objects to all participating users in the group; a remote cooperation over great distances is also enabled, requiring additionally the camera image of one of the cooperating users. Thus, training in a collaborative group interacting together at the same place or via distance education can be portrayed in a lot of scenarios. Both forms of cooperation can also be transmitted to the participants synchronously, as well as asynchronously. With an asynchronous connection, a later alteration of the augmented world is possible through assigning and storing scene, actions and orientation to a specific frame in the videostream. In this way, a later correction can be carried out to better portray an error or problem and to heighten the learning experience. In contrast, with synchronous learning in groups, collision recognition in terms of a simultaneous access of the virtual object is necessary. By implementing a Collaborative Augmented Reality learning environment, applications in the field of Tele-Teaching and Tele-Training become both synchronously and asynchronously realizable. For a remote synchronous learning environments, the remote user can have the same model of the real world, which has to be augmented, and can interact the same way as a collaborative user at the same site. In the case of the Tetris game, both users have the model of a pen or a joystick for interaction and the board of the game. Another synchronous possibility is to transmit the video images of one user to the remote user. The interaction can be done with an interactive graphic and will be sent through the event mechanism, as well. In the case of face-to-face collaboration, a pen with markers is used for 3D interaction. This allows a very natural interaction mechanism with the game. In a later version, speech recognition will be integrated to enable a multi-modal interface and, according to Glasser, we can improve the effectiveness of remembering information with the aspect of speech.

But it is also possible to realize asynchronous teaching and training collaborations. We need to store the camera images of at least one user and also the actions like translations or rotations of the scene, the orientation of the virtual objects and the name of the scene dependent on the frame number of the images. If we store the images of more than one user, we can also switch between the views of the users. In this asynchronous scenario, the images are retrieved from memory, are identified by the corresponding frame number and are superimposed with the formerly valid objects. However, the virtual objects can be altered later as to position or orientation, or other virtual objects can be loaded. In this way, errors can be better explained and understood. This can occur on-site in the real world by projecting the virtual objects time-dependent to the recording in the real world with the help of a head-mounted display (HMD), or in a remote scenario, displayed on the desktop together with the video content. Discussions concerning a particular action could be subsequently initiated and problems better be solved. Explanations could be offered as to the point in time when something was done wrong and how it could be made better could be visualized.

The Tetris game supports multiple users playing one game. This simulates group discussions and the connection to a remote teacher collaborating with a student while assembling a mechanical engine. It also handles the problem of common competing interaction. The actual field of view of other players and their different games can be integrated into the view of a teacher. One special view can be selected and the interaction can be switched to the selected game. This represents the scenario of a master who supervises several trainees learning the AR system or being instructed how to handle a machine. The master can select the view of a trainee and can give him advice and support in his augmented environment. As a result, a master can supervise a few learners.

Another aspect is the view of common and private data by the collaboration participants dependent on the expertise of the users. Thus, each user of the learning collaboration can customize the view to his needs or to see different aspects of the same thing adapted to the circumstance. Converted to the Tetris game, the users play the same game and get a private view of the game and their interactions. The common data is the next piece and the score. The users can add and customize visual aspects to their needs like the deleted levels or the time played.

How to visualize the result of cooperation by a learning group will be a further step in this work. If many people play the same game remotely, a player wants to know why the piece moves to the left even though he/she pushed the piece to the right. Therefore, the representation of the results of the interaction is an important field. The best way to do this will be to use multiple indications like color, arrows and numbers (Fig. 2) or the player can get haptic feedback.

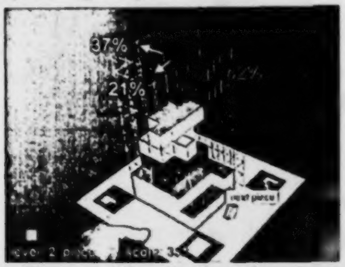

Figure 2: Visualization of results

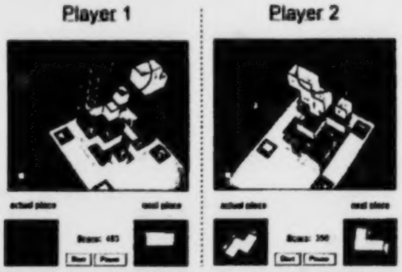

Figure 3: Collision detection and Semaphores

There are a lot of difficulties to solve in sharing virtual learning environments. Mutual exclusions have to be implemented and collision detection is needed. Semaphores have to control the access to interaction mechanisms. This problem can be approached in one game for two players, where two pieces are falling down (Fig. 3). Each person can interact with one piece, gets personalized information and has to coordinate his work with the other player while getting information when collisions are detected.

Conclusions

We have analyzed specific scenarios. The needed technical and interactive requirements for these scenarios have been derived. A collaborative AR environment was suggested and realized prototypically as a test system for a Tetris game. The system can be used in a wide range of educational settings and it allows an asynchronous, as well as a synchronous access e.g. to a learning environment that can be used remotely for distance education or in a collaborative group interacting together at the same place in a master – trainee scenario. It is possible to login dynamically to the same group and share the augmented space with other participants at any given time. It was observed that the fast event mechanism can provide the information to other participants in real time by pushing the information. A further step for the future is to evaluate the outcome of this cooperative game and to transfer these initial results to education applications. But until then, a lot of experiences can be garnered and further research work completed.

The Effect of Hypertext Structure on Recall

Kay Wijekumar, Ph.D.
Assistant Professor
Information Sciences and Technology
The Pennsylvania State University Beaver
kxw190@psu.edu

Abstract: Even though hypertext is the medium of the fastest growing information interchange in the world - the WWW, no research exists on what adults recall from reading information from hypertext. This paper presents preliminary findings from a research study to investigate this.

Introduction

Reading information from printed text or the WWW appears to be the most common method of information retrieval for web-based learning environments or informational web sites. For example, most on-line courses provide notes for students to review and/or web sites for them to visit as activities to collect information about the course. Web sites also serve as the information dissemination methods for many non-profit organizations like the American Cancer Society, American Lung Association, The Sierra Club, and many others.

The research to inform the development of these sites has concentrated on the navigation patterns (McDonald & Stevenson 1998), colors, text size, and layout (Park & Hannafin, 1998). But the organization of web sites but has completely overlooked a large volume of research on prose processing by adults in printed mediums.

Research on prose processing and recall in traditional printed mediums has contributed a lot of information to design and development of printed materials. Text structure has been shown to affect recall of passages by readers with varying backgrounds (Kintsch 1978, Meyer 1975, Meyer et al., 1980). Elements at the higher levels (main ideas) in paragraphs are remembered more than those within. Signaling of main ideas affects the recall (Lorch, 1989; Lorch et al. 1993; Rickards 1997). The readers background knowledge on the topic, verbal ability, educational level, interest, and age have also been shown to affect reading, recall, and use of the information (Meyer et al. 1989, Meyer et al. 1997).

Hypertext is a new format which has taken over a large role in the dissemination of information through its accessibility on the WWW. Hypertext is the medium of web-based learning environments and also the source of information for most web sites. But how is hypertext different from traditional printed text.

Hypertext allows the creation of documents that can contain audio, video, images, and links to other documents (Conklin, 1987). These links to other documents usually appear in different colors and can take the reader to a completely different document. This organization and ability to link documents has the potential to allow the users access to large volumes of interconnected information (Spiro et al., 1992). However, this can also result in some negative side effects (Wenger, 1997). For example, in the traditional text medium highlighting a word or placing the word at the beginning of a passage signals users that it must be important. Would a link which is highlighted by its color serve the same purpose? Reading in traditional text is usually in a linear format and therefore can be organized accordingly within the minds of the reader. Would the links confuse the reader or jumble their organization of the information read?

Objectives of Research

The purpose of this research was to study whether links highlighted by color server as signals to the readers and whether hypertext organization using framed menus affected recall.

Research Design

To study whether hypertext organization affects the recall we used three passages used in many studies conducted by Meyer et al. (1997) and modified them to be presented in a hypertext environment. The first condition presented the entire passage in one screen with no links (This condition was very similar to the standard printed prose). The second condition had links embedded in the text but the participants did not follow the links. The third condition used a frame based presentation with a menu on the left allowing the user to navigate through the information.

Forty two participants over the age of 18 volunteered for the research study. Each participant was given a Quick Word Test (used by Meyer et al. 1997), a pre-experiment questionnaire to identify their prior knowledge on the topics, were randomly assigned to the experimental conditions, after reading the passages they were given a break and were asked to recall as much information as they could from their hypertext reading.

Data analysis was done using a 3 x 2 factorial design to compare the recall score (dependent measure) for each experimental condition (Plain Hypertext, Linked Hypertext, and Frame Hypertext) x (High Verbal Score, Low Verbal Score).

Results

Results showed that 80% of the participants had high verbal scores and there were no significant differences in recall between the experimental conditions. The low verbal score participants had significantly lower ($p < .01$) recall in the linked hypertext conditions than the plain hypertext. There were no significant differences between the linked and frame hypertext conditions for the low verbal score participants.

Conclusion

These preliminary results suggest that high verbal ability adults' recall of information from reading hypertext in plain, linked, or framed options do not differ significantly. However, low verbal ability readers are affected by the different conditions. These findings are similar to those results reported in printed text mediums where high verbal ability adults were not affected as much as the low verbal ability adults in different prose formats and recall.

We continue to collect data to further explore the results on low verbal ability adults and whether the colored links serve as signals and affect their recall. A fourth experimental variable has now been added where the participants follow the links in the documents and read the linked documents before completing the recall test.

Information Technology's Role in Biochemical Systematics

Abstract

Bioinformatics is a new discipline that lies at the heart of the recent advances in understanding of genomic and proteomic systems. The NIH defines bioinformatics as "research, development, or application of computational tools and approaches for expanding the use of biological, medical, behavioral or health data, including those to acquire, store, organize, archive, analyze, or visualize such data." Developing course material for learners trained in traditional medical, biological, and information systems disciplines bring new sets of requirements to the e-learning world.

Today practitioners of any discipline in the molecular biosciences find themselves in an exciting and challenging situation. Current research in the biosciences is revealing molecular mechanisms of complex biological processes in an increasing number of areas. Knowledge of the molecular foundations of biological processes is increasing exponentially.

A major recurring theme is the relationship between molecular structure and biological function. Current studies of complex biological processes utilize information from assemblages of linked databases and electronically accessible journals available on the Internet. The use ofInternet based resources gives practitioners information soon after it is made available to the research community. This rapid access to new knowledge is unprecedented, and has changed the way those interested in the molecular Biosciences do their work. Structures and function are increasingly expressed in digital form, and exploring the molecular foundations of complex biological functions requires the application of many techniques from information technology. These techniques have come to be termed bioinformatics, defined by the National Institutes of Health as "Research, development, or application of computational tools and approaches for expanding the use of biological, medical, behavioral or health data, including those to acquire, store, organize, archive, analyze, or visualize such data."

Even the simplest cell, viewed from a molecular perspective, is a highly complex macromolecular assemblage. The assemblage of these systems occurs auto-catalytically, the assemblage is reproduced with fidelity, and these characteristics and capacities are routine attributes of even the simplest of life's forms. Add to this the fact that these are complex adaptive systems, having a capacity to produce progeny that have characteristics and functions different from themselves, and the task of unraveling the molecular events, relationships, ordering and controls that provide this reality begins to appear impossible. We, of course, expect that it is not, and deep studies of these processes are now underway. Techniques are available now, which allow direct activation and deactivation of cell-signaling pathways. It is this level of systems study that brings the field of biochemical systematics to the forefront of current research in molecular bioscience. Most practicing biochemists do not have an extensive background in information technology; similarly most IT professionals do not have extensive backgrounds in biochemistry. The authors of this paper have collaborated since 1998 on the development of a graduate course in biochemical systematics designed for students from both backgrounds. The presentation will use the course structure and features as a vehicle for discussing the deeper issues involved in preparing IT professionals for careers in this new field.

From its inception, this course has included a number of functions from the information technology domain. The course is referenced to two modern textbooks, augmented by a course web site that provides current links and interactive tools to aid in the visualization and manipulation of molecular representations (see http://www.america-tomorrow.com/gmu/biochem). The graduate students in this program are mostly full-time employees at are biotechnology firms, and the course makes use of alternative assessment methodologies including small group class projects that are delivered in the form of Web or PowerPoint presentations. To facilitate the student interaction on these projects, a number of asynchronous and synchronous communication functions have been provided. The course uses a combination of in-class lecture augmented by the class Web material and the discussion forums. This augmented distributed learning environment (Willet and Keefe, 1998) has proven to be particularly effective as the bioinformatics content moved to prominence. Rather than a study of chemistry and chemical reactions, the topic has emerged as a study of life.

From a molecular biology perspective, life is a necessary and obligatory output of the universe. Life forms as a result of the universal laws of physics and chemistry. It should arise when and where conditions are appropriate to the hierarchical molecular assemblages that promote the development of complex, dynamic auto-catalytic self-replicating systems.

Any system that establishes order in the midst of a universe that thrives on maximizing disorder, requires absolutely a ready and continued source of energy for both its initiation and continuance. In a study of life from this perspective, several fundamental concepts become core to both the system's description and any real approach to its understanding. Most Biochemistry texts break out these fundamental areas of knowledge, essential to life processes as we know them, in similar fashion.

Most modern courses on biochemistry begin with an introduction to the fundamental molecular basis of life, either before or after introducing the concept of the "Cell" which forms in all aspects one of the key precepts of molecular bioscience. How one presents and builds upon the "Cell Theory" of life, depends in some measure upon ones own primary subject domain, and area of personal expertise.

Historically, conceptual materials are presented along the lines of developing levels of complexity. Moving from a presentation of the simple molecular entities that serve as the building materials of cellular constituents, to the complex molecular arrays which provide the functional and structural attributes of cells and cellular processes.

Two broad categories of cells exist, those of prokaryotes and those of eukaryotes. Here *the differences lie in the nature* and constitution of the supra-molecular components of their discernable ultra-structure. Those lacking a membranous envelop encapsulating their genetic material, are defined as "Prokaryotes", those having such a membranous structure surrounding and encapsulating their genetic material are "Eukaryotes".

Keep in mind that viruses and other a-cellular parasitic or symbiotic systems, are unable to self-replicate and require, obligatorily, another cellular system, for their replication. Even the simplest cell, viewed from a molecular perspective, is an indescribably (at present) complex macromolecular assemblage. That the assemblage of these systems occurs auto-catalytically, that the assemblage is reproduced with fidelity, and that these characteristics and capacities are routine attributes of even the simplest of life's forms, adds to the overwhelming nature of our task to understand such phenomena at the molecular level. Add to this, the fact that these are complex adaptive systems, having a capacity to produce progeny that have characteristics and functions different from themselves, and the task of unraveling the molecular events, relationships, ordering and controls that provide this reality begins to appear impossible.

Techniques are available now that allow direct activation and deactivation of cell-signaling pathways. It is this level of systems study that brings the field of bioinformatics to the forefront of current research in molecular bioscience. Information gained at this level of investigation of cellular functions requires and demands the application of tools and methods from applied mathematics and the computer sciences. Modeling now, becomes an essential component of research directed toward an understanding of this level of biological function.

Investigations into molecular determinants of cellular function that are now underway illustrate the import and value of Informatics approaches to understanding deeply the mechanisms of cellular signaling processes. Study of cellular signaling processes, like studies of other signaling processes over the past half-century, is facilitated by transducing information about the process and storing the information in digital form for analysis. This enables analysis using the same probabilistic methodologies that form the basis of much current information science. (Zweiger, 2001).

The investigation of complex, multi-component, dynamic functions of cellular systems is now possible. Such studies employ an array of conceptual and technical approaches in their application. Any review of the current literature highlights this aspect of research in the molecular biosciences. The application of molecular techniques, within biosciences is now universal.

Abstract: Two graduate classes, from different academic programs, were brought together to work collaboratively on the design and development of a Web-Based Training project. The projects were problem-based and derived from students' workplace situations. The classes were supported by a course management system that provided supplemental instruction, communication and file-sharing capabilities, as well as access to common resources and instructor guidance and feedback. Students met with their instructors weekly, and met for an hour of each class with their teams. They continued the team discourse via message boards, chats, and electronically shared documents, all within the course management system. This paper describes this experience and the impact the computer-supported learning environment had on the quality of student projects and recounts some of the stumbling blocks and successes.

Background

Currently, there are two courses being taught that deal with creating documents for the World Wide Web (WWW). One course is taught in the Information Systems (INFSY) curriculum and deals with the technical side of the Webpage in programming and markup languages including JavaScript and XML. The other course is taught in the Training & Development (T&D) program and deals with the effective design of Web-Based Training (WBT) and its application in the workplace. Each courses' requirements included a team project consisting of detailed planning documents and an operational WBT site. The INFSY course required programming documents, while the T&D course required instructional analyses, objectives, and storyboards.

At the end of each semester, Student Evaluations of Teaching Effectiveness (SRTE) forms were completed by each student and the results reviewed. Responses to the written, open-ended questions indicated that students in the T&D design class, while satisfied with the design skill practice, would like to have more skill in the technical aspects of WBT and familiarity with the capabilities of Java, JavaScript, and XML to carry out their designs. Their designs were well-done, but their lack of technical skills prohibited them from fully developing the instructional website project they had designed. Projects in the INFYS course sometimes lacked the structure and organization necessary to be effective, although they utilized the programming languages skillfully.

The INFYS students lacked the instructional design background and the T&D students lacked the technical skills to create functional, professional quality websites. The student projects required by both courses were being evaluated on either technical skill or design, but not both, due to the scope of each course's objectives. Since both design and development is critical to professional WBT, and there is currently no single course that would provide student competency in both, the students become proficient on only one level. Would this be a good application of collaborative learning?

In searching for related research specifically focused on higher education, one study were identified dealing with the effects of collaborative activities on a group of undergraduate students' tolerance toward diversity (Terenzini, 2001). Another study investigated cooperative groups of college physics students working on solving problems in groups (Heller, 1992), but no research was identified that investigated cross-discipline teams in computer-related courses, working on a collaborative project. This study is intended to evaluate the factors affecting the success of that cross-discipline collaborative project activity among graduate students.

If the INFSY students were exposed to good design practices and the T&D students learn some of the capabilities of Web programming, the student experience would be more complete and result in better WBT sites. The collaborative nature of participation on a design and development team allows for peer tutoring opportunities across disciplines and the synergy should result in a better product. It was hypothesized that students would benefit from working collaboratively on a Web-based Training (WBT) project, but some students like team projects and others prefer working alone. Would required participation on a collaborative project put any students at risk?

The Study

The instructors of the two courses worked out a mutually acceptable semester schedule which included separate instructional times along with joint sessions for the collaborative teams to work. Since the students initially lacked the skills to produce the project, the first half of the semester was spent primarily in instruction. The 36 students participating in the study (24 INFSY and 12 T&D students) were introduced to the course management system and to their team members early on. There were five teams with 5 to 9 members on each team. There were at least two T&D students on each team and the teams were mixed in gender. They were instructed to discuss with their team members possible training problems for which they might design and develop the WBT. As the semester progressed and their skills increased, students met with their teams more frequently and for a larger portion of the class session to design and develop these WBT solutions.

The course management system was utilized to create a learning environment where students could communicate through message boards and chats, as well as e-mail to teams, individuals, or groups of individuals. The system allowed the instructor to assign teams and set up the team communications. Students utilized the team file manager most. There, they could upload design and web documents to a common team area accessible only to instructors and members of that team. They were constantly receiving feedback from team members, peers, and instructors through one of these communication conduits.

Results

At the end of the course, the students were asked to complete an online satisfaction survey in addition to the usual SRTEs. The survey was a Likert scale assessment tool of 21 statements where students were asked to rate their own contributions or those of their project partners on issues such as attitude, amount of work completed, correction of errors, level of participation, degree of knowledge, organizational skills, and willingness to participate in another collaborative WBT project with those team members. Of the 14 females and 22 males participating, 50% reported having a Very Strong relationship with their project team members and the same number responded that the work done by their partners on the project was done fairly accurately. In general, they were pleased with the amount of work (61% Very Strong) and attitude toward the work of project partners (55% Very Strong, 25% Strong).

There were mixed responses regarding issues such as technical competency of their project partners (47% responded Very Strong, 42 % Strong, 6% Neutral, 3% Weak) and the reliability of project partners (44% very good, 36% good, 14% neutral, 6%poor). Communication with the team was a problem with only 36% reporting the communication as Very Strong, and 31% reported Strong communications (14% Neutral, 17% Weak, 3% Very Weak).

In addition to the survey, the students made a presentation to the combined classes, demonstrating their final projects. Each project was graded once by each instructor, using the same criteria used for the projects completed when the courses did not collaborate. The INFSY instructor evaluated the programming and technical aspects, while the T&D instructor evaluated the instructional design aspects and the use of principles of screen design. The quality of the projects was very good They followed a more intuitive course and demonstrated a logical application of Web conventions to facilitate learning. Students felt that they had a better grasp of the whole process and that, although exasperating at times, the cross-discipline team experience was valuable in learning a broader approach to instructional Website design and development.

Conclusions

The survey results and comments reflected that students felt that the final project was better for the teamwork, but that working with a team could be very frustrating. Many cited problems with scheduling time together, communications, poor turn-around time of partners, poor corrections of errors by partners, and poor flexibility. In spite of this, they felt that their project partners were fairly technically competent, fairly accurate in their work, completed the work assigned them, had good attitudes and did their share of the work.

The students also felt that they could not have accomplished as much as they did without the supporting elements of the course management system. The instructors were able to track students' logins and course management system usage. Most of the students used all the communications conduits at one point or another and liked the ability to share documents the best. They would post a design or programming document and get feedback or modification suggestions from their team members, make the changes, and post again within a short amount of time. The course management system allowed them to work together at a distance and continue the dialog begun in class, getting peer as well as instructor guidance.

While the collaborative project activity was successful, student support provided by the course management system facilitated the process and allowed student to learn from one another. It encouraged an on-going dialog among the team members and sustained the creative endeavor.

Abstract: Distance education fosters new kinds of collaboration among students and between students and instructors: some unintended. This presentation summarizes parallel studies of distance education community building in asynchronous and synchronous, desktop-video environments. Using observation, focus group response, and reflective journals, the researchers analyzed the interaction among class members and the perceived outcome of that interaction as part of student learning. Results indicate that disengagement or dissatisfaction in synchronous classes caused individual student disengagement with learning process; similar reaction in synchronous classes caused disruptive communities to form among learners that exhibited both internal mores and persistence over several class meetings. Discussion of results includes recommendations for identification and remedy.

Introduction

Distance education is collaborative education. At the least, the predominant design among recent prescriptions for designing or administering distance education post-secondary classes and training programs recommends collaborative strategies for learner activity and for the virtual classroom. Distance education, of course, means education facilitated by recent technology. It is important to change, but equally important that no one be left behind, or be made to feel left behind, in the course of changing (VanDusen, 1997).

Among those areas examined in recent studies of distance education is the intriguing nature of community or interaction among students. Russell's *No significant difference* study, now in its fifth edition (2001), summarizing more than 350 studies dating back more than a half century, demonstrates that design, rather than proximity, has always been the key to successful instruction. Measuring outcomes remains a normative business, however, with the WICHE (Western Interstate Commission for Higher Education) standard of "outcome significantly equivalent to traditional instruction" as the goal of distance programs.

Nonetheless, concern about the image of the learner, deprived of companionship or access because of the medium, strikes at core of traditional views of college classes.

This report presents research conducted in parallel studies examining incidental learning in two kinds of university distance education: asynchronous Internet and desktop video classes, and what happened to community in them.

The Studies

A dichotomy may exist between teaching and learning in online distance education courses and desktop video conferencing courses, for, incidental learning outcomes not identified as part of the formal curriculum are clearly evident (Furr 2000, McFerrin 1998). Learning to use technology and individual and group attitudes and behavioral patterns are two important outcomes. And they aren't always desirable. Technology problems and lack of sufficient class interaction and participation cause students to become distracted from focusing on course content. While frustration levels in students in the DVC courses are higher than those in the online courses, elements of frustration exist in both (Furr 2000, Hara & Kling 2000, Johnston 2000, Robertson 2000, Collins 1999, McFerrin 1998).

Asynchronous Online

McFerrin (1998) examined the incidental learning activity in an asynchronous online course. Two types of incidental learning outcomes occurred. The first developed from the students' learning to use the technology itself. The second type of incidental learning centered on certain areas of the students' personal development. An increase in time management ability, self-directive behavior, self-confidence, and self-discipline occurred. Students in the online course exhibited an increase in self-knowledge and a belief that more new goals can be set and successfully accomplished.

The results of the study illustrated the importance of incidental learning in an asynchronous online course. Both students and instructors must see the value of incidental learning to the student and must foster its development.

Desktop Video Conferencing

The second study (Furr 2000), addressed learning in desktop video conferencing (DVC) courses, a relatively new delivery medium for college courses. Because DVC is a new technology, even less literature targets its effects on teaching and learning environments (Cifuentes et al. 1999, Merisotis & Phipps 1999, Thorpe 1998, Mize 1996). The DVC study was structured to replicate the 1998 study in asynchronous, online college instruction. The researcher examined the experiences and perceptions of participants--faculty, students, and staff--in five desktop video conferencing courses

Consistent with McFerrin's findings, the researcher discovered two types of incidental learning outcomes not identified as part of the formal curriculum: learning to use technology and individual and group attitudes and behavioral patterns. Factors that afforded positive experiences and perceptions were convenience and reduced driving time, informal class atmosphere, small classes, prior computer skills, access to a computer and the Internet, internal student traits, and instructor facility with technology and distance education pedagogy. Factors that diminished a positive experience were technical problems, insufficient administrative support, inadequate training, weak proctor system, and negative student behaviors.

Unlike McFerrin's study, Furr (2000) found a higher level of frustration among participants in the DVC courses. Of the 52 students polled at the semester's end, 48% said they would take another DVC course, 17% said "no," and 21% said the type of course offered would determine their decision. The remaining percentage of students either did not answer the question or said they were graduating. Of those willing to take another DVC course, convenience was the top-cited reason. They were also willing to forgive technical problems, believing "bugs would be fixed." Nonetheless, a sizable number of students reported either a negative or neutral stance regarding DVC. "It became ongoing and public and diminished a professor's authority and respect," one proctor said. One instructor noted that the array of technology available to students during class and the added focus and concentration needed for instructors to deliver a course and for students to process the content prompted students to go "mentally off-line."

If a positive outcome is to occur, then DVC requires substantial technical training and support, administrative support for faculty, and a strong proctor system. Importantly, educators must continue to refine the pedagogy of effective teaching and learning with DVC.

As with any program, monitoring participants' experiences and perceptions is critical to success. Fulk (1993) proposed that an organization's members could be expected to develop coordinated patterns of behavior based on observations of each other's behaviors, the consequences of behaviors, and emotional reactions. Detecting those patterns, whether faculty, student, or staff, is crucial to avoid falling into the trap of the "rapture of technology" and failing to assess how different learners use technology differently with different and sometimes unexpected results (Ehrmann 1998).

Similarities and Differences

The two studies highlighted similarities that existed between these particular asynchronous online and synchronous DVC courses, including the need for students to be self-disciplined, self-motivated, and patient; variance in computer skills and technology accessibility that existed among the students; use of email for communication between student and instructor; compulsiveness of students; unrealistic expectations of students; lingering technology frustration; vulnerability of at risk students; lack of driving time and expense devoted to travel; newness and niftiness of the technology; expense to operate courses successfully; smaller size of the classes; and lack of university-wide system for student evaluation.

The studies illustrate several key differences between the two media. In a text-based online course, students tend to be more careful in their comments about other students, the course, and the instructor. In a DVC course students at remote sites can informally converse among themselves, with negative behaviors and comments often going unchecked. A strong proctor system, particularly with younger or more immature students, is key for DVC. In a DVC course, negative individual attitudes and behaviors can affect an entire group, with an instructor unable to monitor individual and group behaviors simultaneously. Classroom management issues and strategies become accentuated in DVC courses. In an asynchronous course, students understand the "transactional distance" between themselves and the instructor and do not expect immediate, real-time feedback. A DVC course gives students the illusion of one-to-one contact with the instructor and active participation. When a student's electronic raised hand or comment in the chat box goes unnoticed or unacknowledged for even a brief time, students tend more easily to disengage from class. Students in online classes are accustomed to and expect a primarily text-based system, whereas the camera and monitor in a DVC class prompt in students a "TV" attitude. However, current DVC technology with its small video window and jerky transmission often relegates faculty and other students to tiny, out-of-focus talking heads.

Boredom and disengagement again can result if students are not themselves focused, motivated, and disciplined. A DVC system requires more technical support during class for both the instructor and students at remote sites. While an online class can weather downtime, a DVC course cannot. A DVC course requires more faculty technical training and preparation for technical contingencies. In an online course, students can choose the time, pace, and duration of their course interaction. In a DVC course, the hours are set just as in a traditional course. Being tethered to a computer for two to three hours and staring at a computer screen can be physically tiring and boring, conditions ripe for frustration and disengagement. For DVC courses, changing activities and frequent breaks are key.

Conclusion

College education has always been, to a certain extent, a process of forming communities of learners. Isolation is a frequently-cited disadvantage of distance education (Olgren, 2000) and a common cause of students' non-completion (Holt, 1998). Ironically, these two studies, taken together, demonstrate a reciprocal relationship between engagement and isolation: students in asynchronous classes, engaged with distant colleagues or mentors, were not deflected by the virtual enticements of the Internet; however, synchronous students, in the company of dissatisfied companions, became themselves distracted, regardless of the potential of their class to engage their interest.

The two studies highlighted the differences and similarities in learning and teaching environments fostered by the two different delivery systems, especially in the area of behaviors. The intriguing nature of community or interaction among students is underscored. Although "good teaching" has many universal tenets, the notion that faculty or students can seamlessly transfer from the traditional classroom to varied electronic formats should be dispelled. These findings underscore the importance of specific faculty development, curriculum planning, and administrative support for distinct electronic venues.

Cheating an Online Test: Methods and Reduction Strategies

DR. JOSEPH WINSLOW
Coastal Carolina University
College of Education
P.O. Box 261954
Conway, SC 29528
jwinslow@coastal.edu

This paper reports findings from an empirical study investigating the degree to which an online test created using a popular web-based testing development tool—*Coursebuilder for Dreamweaver MX*—is susceptible to student cheating. Results indicate that students at all computing ability levels are capable of discovering viable cheating methods, even when specific anti-cheating measures have been implemented. However, these measures can significantly reduce the quantity of online cheating occurrences. The paper concludes with a discussion of additional derived strategies for further reducing the probability of cheating online. Designers, developers or trainers utilizing web-based testing systems should take interest.

Context

For more than two decades, computer-based testing (CBT) systems have been used to administer interactive objective assessments to students at all education levels. Supporters of CBT have noted many logistical advantages over traditional test administration—including flexibility of setting and format (Bonham et al., 2000), reduction in testing time (Bunderson et al., 1989), automatic grading and performance tracking (Greenberg, 1998), adaptive remediation (Meijer, 1999), psychometrics (Whalen, 1998), and comparability to paper testing (Bocij, 1999; Bugbee, 1996). Despite these advantages, the use among faculty has often been limited to either the purchase of proprietary question data-sets from textbook publishers, or the development of custom assessments using expensive and complex authoring systems (Byers, 1999).

Fortunately, the origin of the Internet as an open-source medium has recently undermined the dependence of educators on proprietary systems. Standardized technologies like HTML, XML and Javascript have been integrated into inexpensive, intuitive authoring tools easily mastered by non-programmers (Byers, 1999). As a result, web-based testing (WBT) systems are increasingly common components of Internet-delivered courseware (Cooper, 1999). However, these same standards that facilitate innovative faculty development efforts also provide tech-savvy students with new ways to cheat. The need to identify these online cheating methods and the specific technical vulnerabilities they exploit thus becomes critical to the sound instructional design of WBT systems.

Although cheating within the context of WBT is not a well-studied domain, existing research on conventional cheating provides a useful schema through which it may be examined. Cheating at the undergraduate level is a very prevalent and very documented phenomenon. Newstead et al. (1996) reported survey data from 943 college students that indicated cheating was "widespread," especially among men and less able students. In a study of 480 undergraduates from two colleges, Graham (1994) found that eighty-nine percent had cheated at least once. Hollinger (1996) found that over two-thirds of undergraduate students had participated in some form of "academic dishonesty" during a sample semester. Lord (1995) reported that over seventy-five percent of students enrolled in college science classes admitted to cheating on large exams and major projects, whereas Kerkvliet (1994) noted that almost half the students (n=443) in undergraduate economics classes from two major universities have cheated on at least one major examination.

The psychology of cheating is also well investigated, with researchers consistently noting that factors most positively associated with cheating are extrinsic. For example, in a recent meta-analysis of 107 studies on cheating, Whitley (1998) found that the strongest correlates of cheating include an expectation of success and anticipation of reward, as well as a perception that social norms support cheating. Nowell (1997) reported that cheating is unrelated to gender, religion or grade point average, but is positively associated with poor performance in class. Similarly, Graham et al. (1994) found that attitudinal variables were better at predicting cheating behavior than were background variables.

Prevention strategies recommended by researchers have generally advocated developing student compliance with value systems. Instituting honor codes, for example, has been noted as an effective countermeasure (Schneider, 1999; Paldy, 1996). Other researchers have delineated less formal but equally values-driven methodologies, including academic integrity codes (Alschuler, 1995), professional integrity development (Odom, 1997), and the implementation of ethics courses (Warman, 1994) or ethical decision-making frameworks (Booth, 1992).

One domain of technology-centric cheating that has received attention in the literature is online plagiarism. Researchers have noted that the Internet facilitates an increased ability to commit plagiarism and academic fraud (Van Hartesveldt, 1998), either by copying and pasting text directly from web documents (Drogemuller, 1997), or downloading previously written and scored compositions from online paper mills (McCollum, 1997). Recommended online plagiarism prevention strategies are varied, and include teaching students about copyright or intellectual property issues and scholarship (Walker, 1998), selecting relevant paper topics and insisting upon full referencing (Drogemuller, 1997), using digital portfolios for combined assessments (Sherry, 1997), and using the Internet to "preview" possible plagiarism (Carnevale, 1999).

What this presentation will include

The purpose of this paper is to report findings from an empirical study investigating the degree to which students were able to cheat an online objective quiz developed using a popular standardized courseware development tool, Coursebuilder for Dreamweaver MX. Three questions of primary interest to the researcher included:

(1) are there any differences in the quantity of cheating methods used between two versions of the same quiz (secure and not secure),
(2) which cheating methods are most common, and
(3) does prior computing experience relate to quantity of cheating methods?

As web courseware development tools continue to evolve, and as individual faculty take greater responsibility in the development of their own custom assessments for online delivery, answers to these questions are critical to the derivation of specific strategies to reduce online cheating.

This presentation will detail the major methods, findings and implications of this unique study. The methodology utilized to invoke student cheating will be described. Both versions of the quiz (secure and not secure) will be presented, and more importantly, all major cheating methods employed by students will be demonstrated.

From these cheating methodologies, strategies for preventing online cheating will be derived and discussed. These strategies will include both technical and non-technical methods to reduce the probability of online cheating. For example, issues to be examined include interface design, user authentication, file security, content management, as well as online testing policy and administration.

Like much of the previous research on compter-based-testing (CBT), recent studies in WBT have focused on electronic testing as an intervention effecting typical outcome variables like achievement and attitude. Gretes and Green (2000), for example, found that when students use WBT modules for "practice" testing, achievement on "real" testing improves. The focus of this study is on the use of WBT for "real" classroom-based testing, and as the data abundantly indicate, the test environments investigated are hardly cheatproof.

To faculty, cheating has always been the "problem that won't go away" (Paldy 1996), and to expect technology -based testing systems to be completely impervious is unrealistic. Given Shaughnessy's (1988) conclusion that "very few students deliberately plan ahead to cheat [but] will take advantage of a situation if given the opportunity," as well as McCabe's (1996) observation that technology -related forms of cheating are on the rise, the findings of this study are relevant to any designer, developer or trainer utilizing web-based testing systems.

HARBOROUGH COMMUNITY LEARNING NETWORK A MODEL FOR COMMUNITY E-LEARNING

David Wortley, Mass Mitec, United Kingdom, dwortley@massmitec.co.uk

Abstract: The Information Age is creating many challenges and opportunities for our global society. Paradoxically, the same technologies which offer unrivalled opportunities for mankind to communicate, collaborate and build a rich, equitable and sustainable future, are also creating a divided world in which individual self-interest could lead to the destruction of the human race.

Virtual learning/conferencing technologies offer great hope for the development of social and economic wealth within communities, helping to address some of the less desirable aspects of globalisation by creating an environment in which people can work together to mutual benefit, and strengthening the bonds of stable and fruitful relationships.

The Harborough Community Learning Network project in the UK is a pioneering scheme to explore how HP's Virtual Classroom technology might be used to create a virtual community centre in which all sectors of the Harborough community can learn, work and socialise.

INTRODUCTION

Information Communications Technologies are transforming global society to an extent and at a pace never before experienced in the history of man. It is this level and pace of change which is posing a threat to the very survival of the human species.

Throughout the history of mankind, it is the development of new communication technology which has caused all the major quantum changes in civilisation. The development of language, cave paintings, ancient scriptures, roman roads, the printing press, railways, telegraph, telephony, aviation, radio and television have all played a significant role in the creation of wealth and power. Today, the internet is arguably the most profound development of them all, not simply because it has achieved a faster penetration into society in the developed world than any previous technologies, but primarily because it places the power to communicate and therefore influence into the hands of the ordinary citizen in a way never previously experienced.

Society has always been based on hierarchies and chains of command and control in all aspects of human life, but we are now moving into a networked society in which the power to communicate and influence is suddenly dispersed. Such a massive dislocation of an existing and ingrained social and economic order places a great strain on governance and stability. Mankind has never before had to evolve in a situation so dynamic and rapidly changing.

The now widely accepted dimension of finite environmental resources is a complication which adds to the challenge and makes it imperative that society responds at a global level to protect our species from the danger of self-destruction. It is a situation not dissimilar to a nuclear reaction in which the human atomic elements are impacting on each other with increasing power and unpredictability. Unless we can harness this process into a positive force, there is every danger that it will get out of control with dire consequences.

The solution to this problem situation has to be a massive cultural change towards a recognition of our mutual inter-dependence and a commitment to societal collaboration in the interest of a sustainable future.

E-learning technologies may have a fundamental role to play in facilitating this cultural shift in the dwindling time available to make the necessary changes.

COMMUNITY KNOWLEDGE NETWORKS

One of the paradoxical side effects of the Information Age has been the fact that information has never been more accessible, yet never more difficult to find. We have a far greater knowledge of people and cultures across the globe than ever before, yet we know less than ever about our neighbours. This is a major problem for society because it encourages unnecessary and illogical consumption of valuable resources.

If society was able to easily identify and harness local resources to common social and economic purpose, mankind would be more able to create sustainable communities capable of development without the level of resource consumption we are currently witnessing.

The concept of a community knowledge network based around a physical community perhaps holds the key to our future. The Harborough Community Commerce and Knowledge Network (www.comknet.org.uk) project developed between 1998 and 2000 was a pioneering attempt to explore the viability of using ICT to support the social and economic development of a community.

Many different applications were explored including e-commerce, web portals, discussion forums, mailing lists and web conferencing. It was the potential of web conferencing as an engine of social and economic change which seemed to offer the most potential as a basis for the next initiative.

HARBOROUGH COMMUNITY LEARNING NETWORK

The Harborough District is situated in the East Midlands Region of the UK and comprises two market towns and a total of 90 parishes, most of which are rural villages. The ICT revolution has resulted in a massive loss of services in these villages – Post Offices, banks, schools, stores and public transport have all been victims of the Information Age.

Dramatic action is required to prevent the death of these small communities and further damage as a result of increasing urbanisation.

The Harborough Community Learning Network is a cross sector partnership initiative to establish a community learning and media centre as a hub to a network of rural public access points delivering local knowledge and services and stimulating innovation and enterprise within village communities.

The HCLN project (www.hcln.net) is still in its early stages, but there have already been some exciting initiative holding great promise for the future. Amongst these initiatives is a concept known as "THE Radio with Pictures Show" which is a hybrid community learning environment formed by combining community radio broadcasting with web conferencing to create a highly interactive learning experience.

In the pilot series of 15 broadcasts on the theme of the Information Society, local people joined national and international special guests on a breakfast radio chat show supported by a virtual classroom in which participants could interact with each other and view slide presentations and web pages relevant to the topic.

This was not only a valuable learning experience for the community, but it also began to sow the seeds of an understanding of the situations and problems faced both within the community and in the world at large.

The community learning and media hub has just started its operation and is already attracting significant numbers of people across all age groups and backgrounds into this lifelong learning environment.

As the project develops, we will be exploring in more depth the potential of interactive broadcasting as a community learning tool capable of building capacity and helping this community shape its own social and economic future.

Web-Based Learning from the Student's Perspective

Linda Wright-Smith
Department of Multimedia Design
Cameron University
United States
lindas@cameron.edu

Abstract: The motive for this ongoing research is to create the best possible web-based learning environment for our university's online students. Professors strive to design an engaging virtual environment with enough scaffolding to facilitate learning and the development of critical thinking skills. On the other hand, some students will never flourish with web-based classes; however, because of time and space constraints, many more students will take university online classes. These students can provide us with feedback that will enable us to make timely changes in how we present tacit and theoretical knowledge. Additionally, the feedback can promote changes in how we motivate students to participate, interact, and communicate in our virtual classroom. A combination Likert-scale and open-ended questionnaire with follow-up interviews is being used to see online classes from the students' perspective.

Introduction

Our undergraduate and graduate students can take classes on campus and some classes online. During the school year, they have a choice among approximately 40 different online classes for which they pay forty dollars more per semester hour. The Cameron online listing of web classes advises students that: "Students should be aware that online courses generally require more time and self-discipline than traditional lecture classes." However, at this time a few classes such as "Advanced Web Communications" can only be taken online. Boehle, (2002) wrote about her experiences as an online learner and provided a unique "student" viewpoint even if it was actually an undercover reporting endeavor. Very few articles provide this perspective; consequently, I began collecting data from my multimedia design students as they experienced taking online classes. These students quickly learn how to work with a computer in order to develop 2D/3D graphics, 3D animation, video production, web pages, and instructional packages with different graphics and authoring software. However, effective learning online requires more than a comfort level with computer technology. Goldenberg (1999) states that a quality learning environment "involves teachers being sensitive to different learning styles and adapting teaching techniques, showing a concern for the student and generally developing a feeling of awareness and sensitivity between the teacher and all students involved." (p.16). The feedback I was getting from my students indicted that they believed that being an accepted member of the online community helped to facilitate their learning process. Along with the students' sense of community, there should be learning "activities" and choreographed "sets of tasks for students that encourage learning" (Fisher, 2000, p. 108). Hence, the research question evolved into: What is the view of online learning from the students' perspective?

The Study

Goldenberg (1999) notes that there is a sparsity of articles correlating "the connectedness a student feels with a teacher, their peers, and how if it affects their learning of the subject matter" (p.19). One of the features of Blackboard is a discussion board where students can respond to different topics, add new threads, and ask questions of fellow students. Additionally it has a virtual classroom where students and the professor can meet for real time discussions. Feedback from students indicated that the virtual classroom archives were being used as source of intelligence gathering by online students who were unable to make it to the virtual classroom. I make use of the technology to query my student's about their perceptions and observations along with their gut reaction to class. They were offered a 5 point bonus for responding to my inquires concerning their feelings and finishing the survey during the last week of the course.

The student frames of references that I am looking at included:

Interaction – Lack of Interaction
Empowerment – Dis-empowerment
Support – Lack of Support
Advantage – Disadvantage
Compatibility – Incompatibility

In addition to the queries, I provided an online survey for my online class to start developing a picture of online learning from the students perspective. The pilot survey consisted of a Likert scale questionnaire and the following open-ended questions:

17. Compare the exchange of ideas online to the exchange of ideas in your typical classroom.
18. What drives you "nuts" about your online class? (One online student suggested this question.)
19. When Blackboard is inaccessible how does it affect you?
20. What problems are you encountering in your online class?
21. List the advantages of taking an online class.
22. List the disadvantages of taking online class.
23. How do you develop rapport with your online professor?
24. If you were the professor, what changes would you make in your online class.

After one semester, I decided to extend this survey to include all online students at the university. Two of my undergraduate students, Wendy Baggett and Patricia Davis, helped to develop the survey for all the web-based student population. Then, Wendy Baggett used Web Surveyor to make the survey available to all online students. The students had room to make comments and answer open-ended questions. When the survey was posted, we asked the online professors to point out the site to their students.

The following pilot questionnaire was used.

Online Course Questionnaire

The information in this section is to ensure that we have sufficient diversity in respondents.

Class Taken:

Age: 15-19 20-24 25-29 30-34 35-39 Other

Sex: Male Female

1. What do you feel is the best thing about taking an online class?
2. What made you decide to take an online class?
3. Other than your online course, have you ever gone online to access instructional material on how to do something? If yes, please explain.
4. Please describe what your comfort level was while participating in the online course, as opposed to how you felt while participating in a traditional classroom setting?
5. What are your feelings towards the use of computer technology? Please explain.
6. What were the factors that helped to promote peer interaction in your online course?
7. While in your online course environment how easy or hard did you find it to follow the navigation of the course? Why or why not?
8. Did you ever feel overwhelmed while participating in your online course? Please explain.
9. If you had the choice to take the same course again, but you had the option of choosing between a traditional classroom and the online course, which one would you choose? Please explain why?
10. Compare the exchange of ideas in your online course as opposed to participating in a traditional classroom?

11. What was the one thing that drove you "nuts" about your online class?
12. Did you encounter any problems during your online course? Please explain.
13. Please list what you feel are the advantages of taking an online course.
14. Please list what you feel are the disadvantages of taking an online course.
15. Do you feel you were able to develop a rapport with your online course professor? Why or why not?
16. If you were the professor of your online course, what changes would you make to the course?
17. If you were conducting this interview, what question(s) would you ask that I have not?

Results

Online Class Results

The return rate in my online class of 22 students was a 100%. They demonstrated the gamut in adjusting to the online class. They did provide useful data for changes in the present online class. For example, we used a digital camera to take everyone's picture and I am making an online class portrait. Below are some of their comments.

"In the future I will probably not take too many online courses because I prefer to have an instructor. I do however like the flexibility of when I use the computer for class."

"I really don't like online classes, I guess because I'm so lost."

"You remember that I referred to the class as nebulous. It's nebulous in that it's this big thing that isn't solid and is floating in a void. You know it's there, but you're not exactly sure what to do with it or why."

"It is just difficult not having you in the lab with us for immediate person to person contact when we have problems that we cannot describe on line. Some things we just have to show you what we mean as we ask the question."

"I got into the test and only got to the second question when my ISP booted me out. I hadn't answered anything and I didn't even get to read the third question. The website wouldn't let me access it again."

"I have always been able to absorb and retain what's been given me in lectures combined with my note taking, so without those learning tools I feeling kind of out of place."

"I must say that in the beginning, I was confused and frustrated about some of the things that were required or being required, but as the year went along things became so much easier that I couldn't believe it. I really think that most of that was due to my attitude adjustment."

"This is a wonderful class. However, it is difficult when there is not an instructor right there to see what difficulties we may have on the spot."

"Well I must admit that I am not as panicky as I was in week one...but that in it self makes me panicky. I still feel somewhat stranded, the tools are there but I am still unsure of what is expected. The discussion board is very helpful. I enjoy the interaction with other students."

"I also like how our graded exam is on the screen right after we take it."

"I don't like this set up at all. I personal think the department should've offered at least one section of this course in a regular classroom setting, instead of all of them online. ...I'm totally lost. I just now realized that I'm a week behind."

Web Surveyor Questionnaire Results

The Web Surveyor questionnaire did not get a response across the different academic disciplines. Our return rate of the actual online student population was low. Most online professors did not send their students to the web survey site. On respondent noted that the best thing about his online class was that "I am in Korea so it is helpful not having to be in Oklahoma." Statistically, 37 percent of the respondents had taken online classes before. Flexibility and convenience were often sited as the best part of taking an online class. However, one person stated that it "gives me the responsibility of having to learn pretty much on my own, which I have found works better for me."

The comfort level of learning online was good to very good for 60% of the class but 29% had a very poor comfort level. Yet over 50 percent experienced feelings of being overwhelmed while participating in online classes. The things that drove them nuts included the amount of reading required, trying to find the homework sheets, stress from other students getting off target topic, not having the internet in their homes, having to contribute to the discussion board, and problems with enrollment.

Conclusions

For the most part, Cameron University online students also attend regular university classes during any given semester. These students have an opportunity to mitigate any frustrations they feel about an online class by visiting with their professor at the university. This closer physical proximity also provides us with the opportunity to examine their perspective with one-on-one interviews. At this point in the research, it appears that we need to assure online professors that we are not evaluating their teaching skills or knowledge base. Without the cooperation of these online professors, we will not be able to build on the survey and get meaningful results. While researching how student's learn in a computerized learning environment, Burge (1994) identified key categories of learning strategies: "choice, expression, peer interaction, and organization of information" (p.19). As professors we all need to look at the flip side of learning strategies which involves the seven principles of effective teaching by Chickering and Reisser as cited by DeBard and Guidera (2000):

1. Encourages Student-Faculty Contact
2. Encourages Coooperation Among Students
3. Encourages Active Learning
4. Gives Prompt Feedback
5. Emphasizes Time on Task
6. Communicates High Expectations
7. Respects Diverse Talents and Ways of Knowing (p. 22)

The students' perspective at Cameron reinforce the need to develop these learning strategies along with good instructional design to facilitate the use of these strategies. There is also a strong need for a sense of community. One student e-mailed me about his efforts to learn online and end with: "have been having a bit of trouble understanding some of the readings, but some of the other people in class are going to start meeting at the lab for group sessions. It will all fall into place as long as we stick together."

Abstract: We have developed and tested an Artificial Intelligence (AI) program combining textbook of fetal echocardiography, an atlas of ultrasound images, and an expert system to form a single resource for reference and education. It was designed to teach physicians and medical students to analyze a typical ultrasound scan obtained around the 20th week of pregnancy in order to detect congenital heart diseases in fetus. The expert system guides the user through the process of making diagnosis, asks relevant questions, and supports the process of detection of congenital abnormalities. For over two years the expert system was available for free download from the Fetal Echocardiography Homepage (http://www.med.upenn.edu/fetus). We registered over 900 downloads, and we obtained comments and criticism from over 200 medical offices from all over the world.

Introduction

Until recently, little could be done for unborn babies suffering from anatomical abnormalities. Now, improved fetal sonographic and sampling techniques and a better understanding of fetal pathophysiology make therapy for the fetus an option. Many prenatally diagnosed malformations can be managed by traditional means, but some anatomical abnormalities with have predictable, life-threatening prenatal pathophysiological consequences require correction before or immediately following the birth. It is still a common opinion between doctors that routine ultrasound evaluation of a fetal heart during the pregnancy does not decrease mortality caused by congenital heart diseases. Unfortunately this is partially true. The main reason for such situation is a paradox: the detection of congenital heart diseases depends on non-cardiologists. It is the responsibility of obstetricians and primary care physicians who simply lack proper training. It is a serious problem because only in the United States every day about 100 babies born alive have congenital heart disease, and in many, perhaps even in most cases, existence of the abnormality surprises the mother as well as the doctor taking care of her during the pregnancy. Today's modern ultrasound machines provide enough power and capabilities to obtain good images of the heart, but keen observation and understanding of fetal cardiac abnormalities are crucial [Huhta et al 1991]. Today's computer technologies can be utilized to support a process of making diagnoses and improve the rate of detection of congenital heart diseases. The goal of this project is not to convert obstetricians and primary care physicians into cardiologists, but to use computers to teach them how to detect congenital heart abnormalities before baby is born.

Methods

Fetal Echo Expert system is a rule-based expert system [Giaratano et al 1994]. It links together knowledge of several human experts in the area of fetal cardiology and ultrasonography, and contains knowledge from presently available textbooks and publications. The program includes a step-by-step tutorial, a library of congenital heart diseases, graphic images, digitized echocardiograms and an expert system, which can support the process of detection of congenital heart diseases. The block diagram of this program is shown in figure 1.

Expert systems are software technology that has been successfully applied to development of systems that model information processing tasks. The design of a rule-based expert system involves a process of interaction between a domain expert and a knowledge engineer who formalizes the expert's knowledge in the form of inference rules and encodes them in the computer. Since human experts vary in skills and experience, and they often do not know what knowledge they actually used in solving their problems, the process of building of an expert system requires enormous amount of effort and is rather time consuming. Despite of difficulties in creating of such system they have several advantages [Giaratano et al 1994]:

- The expertise is permanent. Unlike human experts who may retire, quit or die, the expert system will last indefinitely.
- The knowledge of multiple experts can be made to work simultaneously.
- The expert system can explain in detail the reasoning that led to the conclusion.
- Steady unemotional, and complete response at all times. This is very important in real-time and emergency situations when human expert may not operate at peak efficiency because of stress or fatigue.
- The expert system may act as an intelligent tutor by letting the student run sample programs and explaining the system's reasoning.

Knowledge that is attributed to intelligent entities more often has the form of uncertain beliefs rather than crisp, indisputable facts. A consideration in the development of an expert system is the ability to deal with uncertainties as they occur when conclusions are only partially confirmed by a piece of evidence. One way of logically manipulating uncertain propositions is to use one of the models of uncertainty.

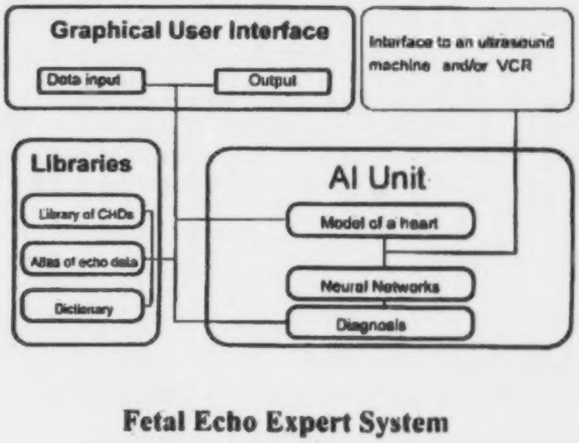

Fig.1 Block Diagram of the Fetal Echo Expert system

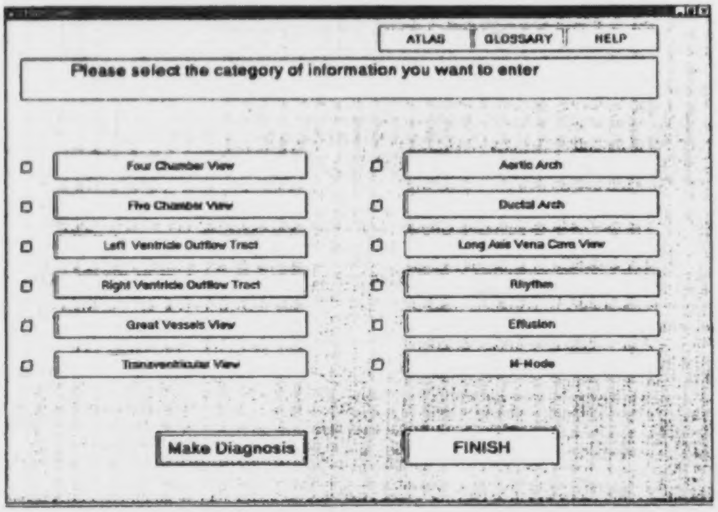
Traditionally subjective estimates of probability and Bayesian processing have been used to specify and propagate uncertainty through an inference network. One disadvantage of this approach is that it requires the assessment of a large number of conditional possibilities and is subject to combinatorial problems in the inference procedure. Another means of logically manipulating uncertain propositions is to use the Dempster-Shafer [Dempster 1968] [Shafer 1976] theory of evidence implemented as support logical programming by Baldwin [Baldwin et all 1986] and successfully implemented in building of expert systems. This algorithm has also been implemented in the Fetal Echo Expert System.

Results and Discussion

BEST COPY AVAILABLE

Fetal Echo Expert System is designed to guide a physician or student through data obtained from an ultrasound examination. It is assumed that user can view the study that is stored on magnetic tape or in the PACS system at the same time he/she is using the program. The questions asked by the program are divided into twelve groups that correspond to the different views of a heart and different techniques used as shown in the figure 2. Every time one set of questions is answered, the user may click on the "Make Diagnosis" button and obtain a suggested diagnosis based on the data entered. The program will also search the library of images and display images and video clips corresponding to the data entered in order to compare them with the ones from the patient. It is possible to change the information supplied to the program and observe how it affects diagnoses.



Please select the category of information you want to enter

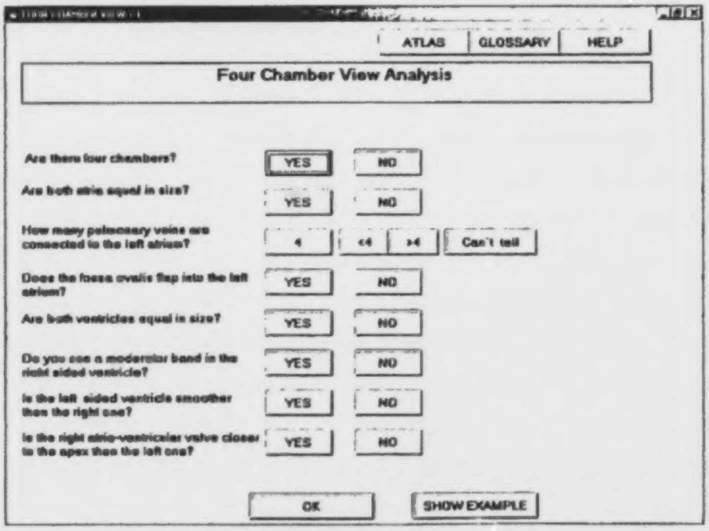
Fig. 2 Choice of views and techniques that can be analyzed before the diagnosis is provided.



Four Chamber View Analysis

Are there four chambers?	YES	NO		
Are both atria equal in size?	YES	NO		
How many pulmonary veins are connected to the left atrium?	4	<4	>4	Can't tell
Does the fossa ovalis flap into the left atrium?	YES	NO		
Are both ventricles equal in size?	YES	NO		
Do you see a moderator band in the right sided ventricle?	YES	NO		
Is the left sided ventricle smoother than the right one?	YES	NO		
Is the right atrio-ventricular valve closer to the apex than the left one?	YES	NO		

Fig. 3 Four Chamber View Analysis

BEST COPY AVAILABLE

The system includes also a "fetal calculator" which helps to determine actual gestational age of the fetus based on the measurements of head circumference, biparietal diameter, abdominal circumference, and femoral length. A large discrepancy between values calculated from these four measurements may suggest other congenital abnormalities such as the Down Syndrome.

The expert system was written in MS Fortran and is linked to the graphics user interface written in MS Visual Basic. The program runs under Windows 95 or higher including Windows 2000 and Windows XP. The program requires a CD-ROM drive, and at least 30 MB of free disk space.

For over two years a simplified version of the expert system (equipped only with a basic library of images) was available to download for free from the Fetal Echocardiography Homepage (http://www.med.upenn.edu/fetus). We have registered over 900 downloads, and obtained comments and constructive criticisms from over 200 medical offices from all over the world. The final version of the program is being prepared now, and it should be available in the first quarter of 2003. At this stage, before regular clinical trials, it is difficult to estimate the contribution of false positive and false negative diagnoses, particularly if the quality of ultrasonograms is not very high. However, preliminary data obtained during the process of testing indicate that regular use of the Fetal Echo Expert System results in a significant increase in the rate of detection of congenital heart diseases in fetus.

Implementing SCORM real issues and resolutions

The idea of the Sharable Content Object (SCO) means that we can create content once and use it where applicable in many different courses. What makes this even better is that someone else can use your content or you can use content that was created by someone else. You can do so because all learning objects' SCOs use the same Application Programming Interface (API) for communication with your Learning Management System (LMS) and use the same metadata for description and searching.

The reality is that current browser security limits the ability for users to create courses with learning objects that reside outside of their domain. We have implemented a technique that will solve this problem, allowing course designers to link to content that resides outside of their domain and thereby eliminating the need to copy content and import it into their LMS.

With this being a reality, we are faced with other major implementation issues such as: How does this affect the end-user experience? How does the content sequencing work? How do you create a seamless learning environment with content that looks and navigates differently from each other? And how do you manage who can access your content? These are the questions and issues we had to resolve as we developed an LMS to manage and deliver SCORM compatible content from multiple vendors for three different organizations.

A Trust Model for Distributed E-Learning Service Control

Yuefei Xu and Larry Korba
Institute for Information Technology [1]
National Research Council of Canada
[yuefei.xu@nrc.ca | larry.korba@nrc.ca]

Abstract: As with traditional face-to-face education, "trust" is an important factor for the interactive e-learning. To deal with security and privacy concerns, this paper proposes a trust model for distributed interactive e-learning applications. The working mechanisms are based on policy-negotiation and public key cryptography. By using this model and proposed approach, fine-grained trust control of common e-learning services can be maintained. The logical model, core concepts, and typical e-learning trust interaction processes are described. An example is also provided to illustrate how the introduced model would be deployed.

Introduction

Similar to the situation in traditional face-to-face education, "trust" is an important factor in interactive e-learning. On the one hand, the e-learning provider requires some basis upon which to make trust decisions of the learner. For example, the provider must ensure that the user accessing the system, from somewhere on the Internet, is someone eligible for the service. On the other hand, the learner needs to trust that the provider and the services will protect personal information, and will release information regarding performance for instance, only to those authorized by the user.

Trust levels may also indicate the learner's levels of motivation or aspiration for learning. It is easy to imagine that students and teachers, whether young or adult, who thrive in an Internet-based e-learning environment that provides mutual trust, respect, and freedom will become a happy, safe harbor for their learning and teaching activities. Trust then will be the most crucial factor for the success of distance learning process with the maturation of e-learning.

In this work, we focus on security- and privacy-related concerns for distributed e-learning systems, where trusted interaction form the underlying requirement between clients and service providers. The concerns can be divided into two main areas. (1) Security: the concerns may include authentication, confidentiality, authorization, non-repudiation, etc. For example, users can access only those resources and services that they are entitled to access, and qualified users are not denied access to services that they legitimately expect to receive. (2) Privacy: mostly, this refers to the privacy of individuals. This includes all the individual's concerns regarding collection and use of personal information.

Trust is also an important topic in information security research. It has received a good deal of attention in recent years [Mass, Y. 2001]. However, very few focus on e-learning related issues. This is remarkable considering the boom of e-learning applications. Based on our study of proposed or applied trust-related protocols and mechanisms like X.509/PKIX (2002), PGP (2001), and KeyNote [Blaze, M. 1999], we propose a policy-based trust model for e-learning. The model supports policy negotiation between parties. The rest of this paper describes the logical model, core concepts and typical interaction processes. We then provide a sample to show how these concepts and models are used to deal with e-learning security and privacy concerns. We end with discussion and conclusions.

Proposed Trust Model

As most e-learning systems are distributed applications, and the typical application mode in e-learning is demand/supply, we consider the Client/Server (C/S) model as the basic communication model. The browser/web-server model can also be thought as a particular type of C/S model. Peer-to-peer (P2P) e-learning systems have some similarities in that in this instance, each peer has both a client process and a server process. Therefore the C/S analysis is still applicable for these applications.

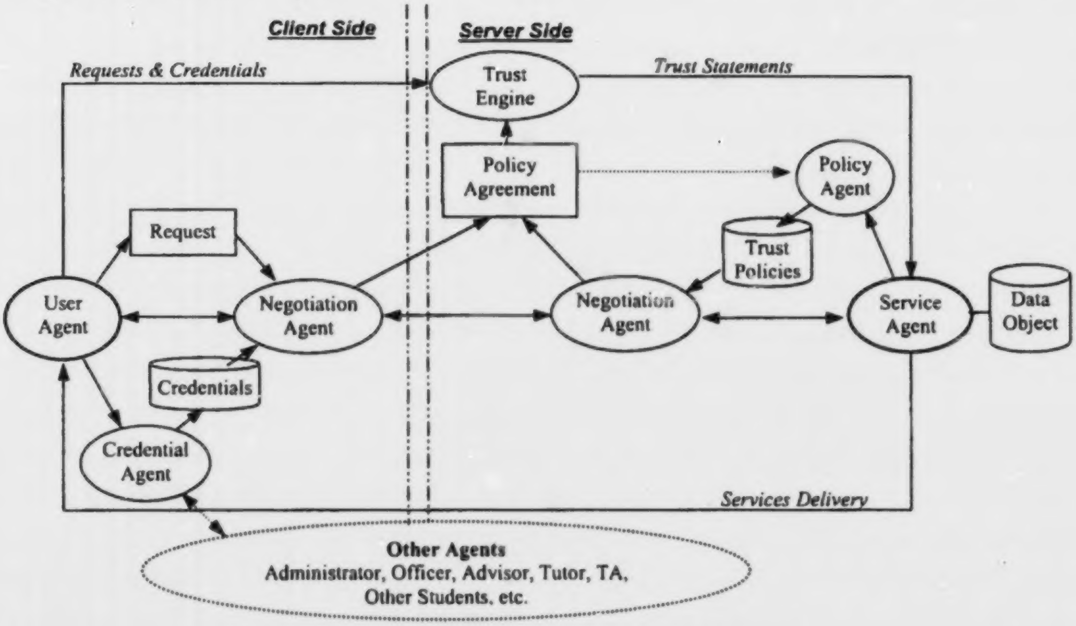
We propose a policy-based trust model for e-learning systems. This trust model provides fine-grained policy-based security and privacy control for e-learning services as well as provisions for policy negotiation. The logical model is shown as Figure 1.



Client Side
Server Side
Requests & Credentials
Trust Engine
Trust Statements
Policy Agreement
Policy Agent

Negotiation Agent
Service Agent
Data Object
Credentials
Credential Agent
Services Delivery
Other Agents
Administrator, Officer, Advisor, Tutor, TA,
Other Students, etc.

Figure 1. Policy based Trust Model for E-Learning Service Control

There are two logical sides for the model: a client side, which request services and a server side, which provides services. The active agent on the server side is the "service agent, while there is a "user agent" on the client side. In most cases, the clients and servers are geographically distributed and connected by a network (Local Area Network (LAN) or a Wide Area Network (WAN)). The network, including the Internet, may be open and unsecured.

On the server side, there are a series of provided services, such as web contents, multimedia, file management, discussion groups, course registration, and so on. Logically, these services can be seen as many computer processes and a series of data objects. For example, an HTTP server process and many html files provide static web content, and course registration service consists of a register process and some database tables or records. When a learning service receives a request from a user, a new service agent is created corresponding to this request. The service agent and related data objects then responds to the request. Each service agent also maintains a series of policies, which specify the security and privacy concerns on the data objects and services. Only requests compatible with these policies can be served.

On the client side, the user also holds one or more credentials, which certify he has some granted rights to receive some services perhaps under limited conditions. For example, before a student wants to register for a course, the student must provide proof of an approval letter (credential) signed by an advisor or supervisor.

In order to initiate a service, the two sides must first form a service agreement. The service agreement states what service is provided to the user and the conditions for that service. Then according to the request contents, the service agent may deliver some data objects to the user or execute some actions on the data objects.

Core Concepts

Role: The Role describes the operational function of an individual or group in the learning system. Examples of roles include: "tutor", and "registrar officer". This concept is used to simplify system management.

Public Key, Signature: Each individual and each role has a unified key pair: a public key and a private key. Both of these are provided by a designated authority. The public key is used as the identification of the key holder. The private is used to form a signature on the credential and request. This key is a key secret to the individual.

Request: The Request describes who wants to do what, stating the "requestor", "objects", "actions" and "signature". For example, the request of "Bob wants to edit the course score " is described as:

Requestor: Bob's public key
Object: course score
Action: edit
Signature: Bob's signature

Credential: The Credential describes what right the holder has been delegated under some conditions, as well as whether or not the rights can be delegated to third parties and the conditions of such a delegation. Credentials are issued by other agents and normally stored on the user side. For example, the follow credential describes "Scott is delegated by Bob to evaluate the student presentation of course CS302 and during school term of 2002-Fall".

Licensee: Scott's Public Key
Object: Presentation
Action: Evaluate
Condition: if (course = CS302 && term = 2002-Fall) then (approve)
Delegation: No
Signature: Bob's signature.

Trust Policy: The Trust Policy specifies who and what operations are authorized on the data objects and the conditions for those operations. The policies are bound with the service on the server side. For mobile services, the policy is mobile with the service. Service administrators initially define policy. An administrator may authorize other individuals to take on the role of defining policy. The policy has the same format as a credential. The difference is that policy is stored with the service. During the life of an e-learning process, some credentials may be accepted and stored with the service if the policy agent accepts them. In this manner, the user doesn't need to provide this credential again when he request some service. This is implied that multiple credentials may be or may not be required when user requests services depending on what policies the service has had. For example, if Scott has the credential granted by Bob to do something, but the system has no policy allowing Bob to do that, a credential on Bob's priority must be provided at the same time if Scott wants to get the service.

E-learning Trust Interaction Scenario

A typical e-learning trust interaction process is described briefly as follows:

- A user browses the service categories, which describe what services are available and simple statements on requirements for receiving the services.
- The user makes a selection requesting a service. A service provider agent is subsequently generated to deal with the request.
- Requests with the available credential types are collected and checked against the trust requirements of the service policy by the two negotiation agents.
- If the request and credential types are not compatible with the service policy, the two negotiation agents will try to solve the conflicts by coordinating actions on both sides via the following actions:
    (a) Let the provider adjust his policy; and/or
    (b) Let the user change his request; and/or
    (c) Let the user seek more compatible credentials from other agents.

- After negotiation, both sides arrive at a joint agreement. The joint agreement reflects the final service policy corresponding to this request and service. The trust engine then checks the validity of user's credentials, and calculates the final compliance value of the request against provided credentials and the joint agreement.
- The result of this compliance is sent to the provider agent as the "trust statement", which indicates the trust decision as well as additional operational requirements.
- The provider agent provides the corresponding services to the user depending on the trust statement. Some additional actions, such as logging, altering, or encryption, are also executed.

Example

In this section, we briefly illustrate how the introduced model and concepts could be deployed using the following example. In particular, the example involves protection of student personal information. Student personal information stored on the server like address, email, telephone, may be changed at any time by the owner. But some critical data, like name, birthday, or nationality may only be changed with the mutual agreement of both the register officer and the owner. The two policies bound with the service are:

Policy a

Licensee: Registrar officer
Object: Name, Birthday, Nationality of personal record
Action: Edit
Condition: if (approved by Owner) then (approve)
Delegation: Yes
Signature: Administrator's Signature

Policy b

Licensee: Owner of personal data record
Object: Name, Birthday, Nationality of the owner's record
Action: Edit
Condition: if (approved by Registrar Officer) then (approve)
Delegation: Yes
Signature: Administrator's Signature

Then a student "Alice" can delegate her rights to Registrar Officer by issue the following Credential *c*.

Credential c

Licensee: Registrar Officer
Object: Name, Birthday, Nationality of Alice's record
Action: Edit
Condition: if (notify Alice@abc.ca) then (approve)
Delegation: No
Signature: Alice's Signature

Request d

Requestor: Registrar Officer's public key
Object: Name, Birthday, Nationality of Alice's record
Action: Edit
Signature: Registrar Office's signature

If a registrar officer holds the credential c, she/he can edit Alice's record by sending the above Request *d* to the personal record management service. The final trust statement will be *(approve and notify Alice@abc.ca)*,

Discussion and Conclusions

People working or learning in cyberspace need mechanisms to develop trusted relationships. Building trust is recognized as a key factor for using and developing the new interaction paradigms, particularly vital for e-learning applications. The approaches and technologies we discussed above could provide a trust decision and enforcement mechanism for interactive distance learning. This work is still at a preliminary stage. There are other important issues to be investigated. In particular, key management, credential version control, and mechanisms for adaptive negotiation among others. Approaches for dealing with these issues are currently being developed within our group. They will be reported in later publications.

A "Thinking Journey" to Mars using Scientific Visualization Technologies : a New Approach to Teaching Astronomy

Yoav Yair
The Open University of Israel, Tel-Aviv, Israel

Yaron Schur

The Weizman Institute of Science, Rehovot, Israel

Rachel Mintz
The Center for Educational Technology, Tel-Aviv, Israel

ABSTARCT

We present a novel approach to teaching astronomy and planetary sciences, centered on visual images and simulations of planetary objects. The "Thinking Journey" concept takes the students to the other planets as travellers, and teaches science through the observation of various natural phenomena. The use of 3D animations and VR-like features greatly enhances the visualization capabilities the teacher can use, allowing simulated flights over the terrain of Mars, studying it as if observing from a spaceship in orbit. The program focuses on the study of the planet Mars, by means of observation, interpretation and comparison to the planet Earth. Students learn to use updated, web-posted images from orbiting spacecrafts, and to recognize similar geological and atmospheric processes on both planets. They discuss astronomic phenomena and discover that the same basic physical laws govern all objects in the solar system.

DIFFICULTIES IN ASTRONOMY EDUCATION

Astronomy and Space Science have a strong appeal to children in K-12 classes. It is a dynamic and exciting science, which is deeply rooted in their everyday life and in the surrounding culture. Teaching astronomy at the primary and secondary school levels is usually a challenge for science teachers, because it contains complex subjects in physics, requires an understanding of three-dimensional geometry and dynamics and demands (from the students) advanced cognitive capabilities. To understand the basic astronomical phenomena such as day and night, the occurrence of seasons, eclipses, phases of the moon and the motion of the planets - they must have the capability of visualizing events and objects as they may appear from different perspectives simultaneously. Astronomy teaching is considered difficult also because of the large amount of facts and details it contains and because some of the concepts seem abstract. Teachers are often faced with the dilemma of what topics from the large curriculum to cover in the limited time frame that is usually allocated.

Children have initial conceptions of celestial objects and phenomena, which are often reminiscent of ancient philosophical ideas, notably Aristotelian geocentric views of the sun and planets (Nussbaum, 1985). Piaget noted many such conceptions in his early studies of child development, and showed that children evoke their own cosmological explanations even at very young ages. As they grow up, their early ideas are probably influenced by erroneous information presented in everyday culture and mass media (Lanciano, 1999) such as science fiction films and TV series. The private cosmological ideas become deeply rooted beliefs, which are often inconsistent with the accepted scientific view. Some of these alternative frameworks continue well into adulthood and are even found in university students. DeLaughter et al. (1998) present a variety of misconceptions found among students in an introductory Earth Science course and cite the famous Shapiro et al. (1988) video that showed Harvard graduates failing in explaining the cause of seasons on Earth. The common misconceptions students have in astronomy may come from factual misinformation, mythical concepts and language imprecision, misinterpreting sensory information and incomplete understanding of scientific processes (Commins, 1993). Without a contextual framework within which to compare astronomical objects (that is, specific tasks or everyday experiencese) , students have difficulty in mentally filing the facts associated with them. They also have difficulties in creating the "big picture" from its various components (Bennet, 1999).

SCIENTIFIC VISUALISATION AND VR SIMULATIONS

In its modern, digital version, scientific visualization links science, technology, computer science, and applied visual arts in the designing of systems that can translate huge amounts of quantitative data into digital graphic images. However, even a rather simple and unique form of scientific visualization in planetary sciences, such as the one introduced by Miller and Hartman (1993), can be a powerful tool for teaching. They drew pictures, views and landscapes of planets, moons and asteroids, based on the scientific data transmitted by the Voyager and Pioneer spacecraft and that obtained by Earth-based telescopes. They provided vivid and spectacular renderings of the clouds of Jupiter and the rings of Saturn, as well as of the volcanoes of Io and the craters of Miranda (moon of Uranus). These images enabled one to tour and study the surfaces and atmospheres of different planetary objects in the solar system, with no other means but a still picture.

Modern ultra-fast computers enable scientists to use ever-subtler variations in color and shading to represent numerical data, that describes different aspects of natural phenomena and processes. Such representations can portray complex phenomena in their entirety and can also consist of a series of images depicting changes over time. In relation to astronomy teaching, scientific visualization can easily become a powerful strategy to overcome the described hurdles. Images from satellites and spacecraft, as well as from the Hubble Space Telescope, become a source to new scientific information. Classroom materials, lesson plans and complete courses have already been developed by NASA (see for example: http://www.thursdaysclassroom.com/) and are widely popular.

The introduction of virtual reality (VR) technologies to desktop computers have greatly increased the ability to simulate and present complex three-dimensional objects and phenomena to the average PC user (Mohler, 2000). This trend coincides well with the notion promoted by Bliss and Ogborn (1989), who stated that computerized simulations act as an exploratory tool and promote the user's understanding of complex dynamic processes. Barab et al. (2000) have presented a virtual solar system as a tool for teaching astronomy.

Lately, Yair et al. (2001) described the application of scientific visualization technologies to astronomy teaching. They developed a 3-dimensional model of the solar system, which includes the sun, planets, moons, asteroids and comets. IN this model, all these objects revolve and rotate in their orbits against the constant background of the Milky Way, the stars and constellations. High resolution NASA images were used and the planetary orbital data were calibrated with great accuracy (Figure 1). The user enters a virtual model of the physical world, where the computer mouse functions as a spaceship of sorts. This permits a journey in the virtual representation of outer space, enabling students to zoom in or out as they wish, easily changing their viewpoint and perspective. Such a learning environment offers an exciting learning experience and facilitates the construction of a scientific concept of the solar system (heliocentric vs. geocentric). Nevertheless, an on-going study at Tel-Aviv University (Gazit et al., 2000) shows that students require guidance and assistance in their interaction with the astronomy VR program, and that they have difficulty in constructing their knowledge without mentoring and mediation by an instructor or a teacher.

THE "THINKING JOURNEY" CONCEPT

A thought experiment ("Gedankenexperiment") is a strong mental tool, used by many scientists to investigate basic natural phenomena. Galileo and Einstein are the most famous examples for the use of this intellectual exercise, discussing questions of gravity and of relativity theory, accordingly. Thought experiments can be used in educational settings as well, providing a powerful stimulus for children studying science (Gilbert and Reiner, 2000).

In a newly developed program, Schur (1998) have introduced the "Thinking Journey" concept to astronomy education. Using images

BEST COPY AVAILABLE

of Earth and the Moon, as well as of spaceships and astronauts, students are directed and coached in a gradual, structured manner, to investigate and discover various subjects in basic astronomy. The approach is based on the works of Feuerstein, Rand and Rynders (1988) and Feuerstein (1998), that focused on the relations between the way children observe natural phenomena and their abilities to understand them. These works describe the connections between thinking processes and the ability to observe a phenomenon and its changes. For Feuerstein, learning science includes observing the organization and regularity of natural phenomena, which is a necessary prerequisite for understanding the relevant scientific facts and content. After learning these scientific concepts, the way is paved for the child to observe the phenomenon in a new manner and to understand it.

In his book, Schur (1998) devised a cyclic learning process that is composed of six stages. The guiding principle of this process assumes that for learning to take place children must undergo a conceptual change, and that they must be performing tasks involving the subject matter, under the supervision and mediation of their teacher. For studying astronomy, children are initially asked to observe a phenomenon (either directly in the sky, or in an image from space). They are then guided (by targeted questions referring to the image) to define and collect the results of their observations. Then, they analyze the data, explain it and look for interconnections between different items. At this stage, the teacher (tutor, instructor) supplies additional information, as well as guidance and counseling. The children then draw conclusions, generalize the observation and look for rules (or natural laws). The last stage is an introspection of the previous stages, to create awareness and as a preparation for a repetition of the process to the next assignment (=observation). This is a dynamic learning process where students are active participants in the acquisition of knowledge, rather than passive recipients of information. The place of the learner is important and explicit throughout the learning process. The learner is not the outside observer who watches the phenomenon. The learner is a part of context.

Since many students have difficulties with mathematical and verbal skills, ways must be found to enable them to interact with the physical environment, while circumventing the mathematical and verbal obstacles. Using pictures of the Earth, the moon and outer space enables students to interact with a congenial modality. Students find the pictorial modality familiar: they are accustomed to it in their everyday interaction with television, movies and computers. Perrig and Kintsch (1985) observe that the pictorial modality is easier for students to remember and to understand than the verbal modality.

COMBINING SCIENTIFIC VISUALISATION WITH THE "THINKING JOURNEY"

An exploratory effort to combine the Thinking Journey method with a multimedia based astronomy program has been carried out at the Center for Educational Technology in Tel-Aviv. The authors have used the "Touch the Sky, Touch the Universe" astronomy CD-ROM (Yair et al., 1997), that is widely used in schools throughout Israel, to develop a special training program for K-12 science teachers. This program utilized the mutual strengths of both components and implemented the cyclic learning process to dynamic animations, MPEG movies and still images embedded in the various items within the software. The positive outcome of these teachers' courses paved the way to applying the new concept to an astronomy program for high-school students who do not major in science.

Taking advantage of the fact that the power of visualization technologies has increased significantly in the last couple of years, we created an advanced program that focuses on a Thinking Journey to virtual landscapes of the planets and moons, as presented in the 3D-VR solar system model described above. The new "Thinking Journey to Mars" program is to be studied by non-science high-school students in Israel and will be a part of the matriculation requirement in science. We chose to focus on the planet Mars because it is one of the most exciting scientific targets of research and the object of dedicated space missions such as the Mars Global Surveyor and the Mars Pathfinder. The up-to-date images received from these space probes were used to create the virtual surface of Mars, and a novel, special "Fly-over" capability enables students to experience a virtual flight above the Martian landscapes. Using a "flight remote control" the user has the ability to fly over the terrain at extremely low altitudes, to zoom-in and out, pan, rotate and tilt the image according to his chosen viewpoint. Figure 2 shows a close-up on the famous Valles Marineris, an immense geological feature in the equatorial region of Mars. This image reflects the new and unique visualization capability of the software, and many important details can be deduced by simply observing the emerging planetary landscapes. Navigation tools and a menu of pre-selected targets (volcanoes, ice caps, mountain ranges and craters, see Figure 3) allows the learner to study in detail the Martian and lunar surfaces in a dynamic, interactive manner. In addition, the user can visit landing sites of spacecraft such as Viking (on Mars) or the Apollo and Luna missions (on the moon, Figure 4), and investigate the characteristics of the landscape and main geological features in these places. This facilitates creating the important sense of "ownership" of the constructed knowledge by the learner, who feels he has control of the learning experience (Goforth, 1994).

The Thinking Journey to Mars builds a narrative that takes the learners to the Red Planet in a scenario that resembles the planning of a real-life mission. They are asked to decide on landing places and to discuss surface properties, as well as to predict weather conditions and astronomical phenomena such as day-and-night and the changing of seasons. By observing Mars from close-by with high-resolution images, and by answering a series of well-guided questions, they can construct a story of a planetary landscape that can be compared with the one they know from Earth. They gradually construct their knowledge of Mars from images, animations and simulations that visualize landscapes that otherwise would have been abstract or alien. Coming "back" to Earth after "staying" some time on Mars can make the learners observe the Earth from a different perspective.

The textbook that is the center of this program (Schur, Brandt and Yair, 2002) uses numerous images of Earth and Mars from space, as well as images of different landscapes both planets. Through questions and activities, as well as by active teacher mentoring, it lets students observe both planets from a new perspective. They can compare the Earth and Mars in numerous aspects, with an approach that is very much like the one used by practicing researchers in planetary sciences. (Planetary geologists often compare the landscapes formed by erosion and ice processes on Earth to those that are observed on Mars, mainly for trying to decipher the important questions of Martian water). This inquiry-based approach drives students to discover by themselves the uniqueness of planet Earth, the characteristics of its dynamic environment and the special conditions that had enabled it become a haven for life. A reflection on the learning process they have experienced through their virtual journeys is considered vital by many researchers (Scardamalia et al., 1989). This is achieved by a set of targeted questions and activities that summarize the Thinking Journey, where students are asked to summarize and deduce the significant changes in their own ideas and concepts of Earth and Mars.

An experimental implementation of the "Journey to Mars" program had started in 2001 in three schools in Israel and will be further expanded in 2002/3. Although the program was originally developed to enhance the scientific literacy of non-science majors in high schools (that is, students who do not matriculate in any of the sciences), it can be easily adapted to any science education program from the 10th grade onwards.

Future research will focus on the ability of students to navigate complex three-dimensional virtual worlds and the whether if they interpret correctly the visualized astronomical phenomena they observe. An extensive teacher-training program had already been initiated and will be evaluated and repeated to increasing numbers of science teachers. We also plan to expand the Thinking Journey concept to the central object in the solar system, that is, our Sun.

SUMMARY

Astronomy and Space science are a natural arena for the use of visualization technologies. Nevertheless, the information a young student may gleam and interpret from watching models, animations and simulations of planetary objects does not necessarily reflect the correct scientific view. Harper et al. (2000) discussed the simulation paradigm and pointed out that experiential simulations such as the described VR tour to the planets have a weakness in that too much complexity can make learners insecure and they lose track of learning objectives. Providing mentoring and carefully constructed activities within the virtual journey can alleviate this weakness, and let the complexity of the learning environment manifest itself and support active, exploratory learning (Goforth, 1994). The use of images, films, computer programs and other means that make use of visual information is bound to increase in the future educational programs (Barab et al., 2000). Using the visual mode of communication requires a different way of teaching, with an emphasis on the process of observation. The combination of a well-guided Thinking Journey with the new 3D-VR models may greatly increase the effectiveness of the learning experience and can guarantee that the student constructs his view of the world in a scientifically correct and enjoyable manner.

Evaluation and Implementation of a Networked Multiple-Choice Question-Posing and Peer Assessment Learning System

Fu-Yun Yu
Graduate Institute of Education
National Cheng-Kung University
Republic of China, Taiwan
fuyun@mail.ncku.edu.tw

Abstract: A web-based question-posing and peer assessment learning system was developed to facilitate multiple-choice item developing peer-assessing, item-viewing and drill-and-practice learning activities. The rationale for the development of the system was described, followed by a preliminary study evaluating student motivation and factors influencing student use of the system. Questionnaires and students' written responses to open-ended questions revealed that via embedding different sources of motivation the system helps cultivatinga motivational learning environment for participants Based on the obtained data guidelines pertaining to instructional implementation were offered.

Introduction

Currently, as computer and telecommunication technologies converge, web-based learning systems are getting popularity and presenting themselves as a promising learning environment for the 21st century. In addition to many of the distinct features that are frequently associated with computers, for instance, immense storage space, high processing speed, multimedia appealingness, learner control, instant and personalized feedback, and multiple-branching capabilities, etc. (Alessi & Trollip, 2001; Heinich, Molenda, Russell & Smaldino, 2002), there are several extra-advantages to have learning activities implemented via Internet. First and foremost, being web-based means that the system is not tied to particular computer architectures or bound to a specific operation system. In other words, web-based learning system is less device-independent (Kahn, 1997). Secondly, the fact that information and resources can be accessed by anyone from anywhere at anytime as long as he or she has a computer with an Internet connection permits global accessibility. Without time and place restriction web-based environments help promote worldwide connectivity and collaboration. Via such interactions multiple perspectives and expertise can be shared and attained more conveniently (Kearsley, 2001). Thirdly, updating, maintenance and management of databases are easy as materials and users' database are stored at the server site (Zhang, Cooley & Ni, 2001).

In view of web's inviting features and its potentials for active learning, a networked domain-independent learning system, named Question-Posing and Peer Assessment (hereinafter named QPPA) was developed in 2001. In general, QPPA allows multiple-choice item constructing, peer-assessing, item-viewing and drill-and-practice for participants for all educational levels for various subject matters in a more instantaneous, anonymous, convenient and environmentally friendlier way. Specifically, with the support of Web technology all items generated by students can be assessed and viewed at individuals' discretion at the very moment the item is submitted. It reduces delay and paper expenditure, and avoids the hassles of collecting, shoveling and re-disseminating items among students as if done traditionally. Besides, without revealing who the question constructors and assessors are, web-based question-posing is less inhibitive and objective assessment among peers would be more easily ensured

In the following section, an overview of the various functions in QPPA is introduced first. As researchers suggested that engaging in the process of questioning is conducive to student motivation (Balajthy, 1984; English, 1998), a study set out to evaluate the motivational value of the system was described next. Moreover, factors influencing student use of the system were examined to help instructors implement such system in classrooms. Finally, instructional suggestions for classroom implementation are presented.

Overview of the QPPA Learning Environment

Mainly, QPPA is comprised of four functions. "*Question-posing*" allows students to contribute to multiple-choice item construction by providing a stem, the correct answer, and three distractors. All items constructed by students are kept in a temporary item bank database.

"*Peer-assessment*" intends to further learning via, from assessors' point of view, critically evaluating others' works, and, from question constructors' point of view, adapting and synthesizing comments given by their peers. Once deciding which item to assess from the "listing of questions" window, students can give their feedback in the "assessment form" window. Some frequently made mistakes in multiple-choice test construction, such as, the stem is not presently clearly, the stem is not in its simplest form, include unnecessary repetition of material in the options, more than one correct answer, distractors are not plausible enough, etc., along with suggestion for revising are provided through a pull down menu in the assessment form window. This intends to, on one hand, act as a set of criteria for objective peer assessment, and, on the other hand, a scaffolding device for writing better multiple-choice items. Students can also type in their suggestions to the item being assessed, and then by the assessor's discretion be sent directly to the original question-poser for reference for further revisions. To control the quality of each and every item constructed by students, a peer assessment process by at least five assessors and with at least half of the assessors rated the question as acceptable was set as the criterion for transferring questions from the temporary item bank database to the formal item bank database

"*Item -viewing*" provides an observational learning opportunity for students to learn from each other by observing items constructed by others as well as the comments/suggestions given by assessors.

"*Drill-and-practice*" allow students to choose the exact number of questions for drill-and-practice exercises. After answering, feedback as to how many questions answered correctly and a review button, which permits further reviewing and learning, was provided.

Beside these four main functions, some additional features were included in QPPA to increase its intrinsic motivational appealingness to users. For instance, Edu-dollars, which, in essence, is a virtual currency, and is accumulated by engaging in different functions in the system; six different ranking lists, that is, players who accumulated the most Edu-dollars, players who contributed the most questions, players who assessed the most questions, players who answered the most questions correctly in drill-and-practice, players whose questions were viewed by most participants, players who spent most time on-line; and statistics summaries on individual and class average performance in the system. Overall, by engaging students in the actual process of writing multiple-choice items and embedding various motivational enhancement features, the system intends to provide students with a motivating learning experience. A preliminary study examining the system's motivational value and factors influencing student use of the system is described in the following section.

Preliminary Study

Participants & the Learning Environment

Two classes of six-grade students (N=52) from one primary school in the southern part of Taiwan participated in the study. Students participated in the study for six instructional sessions. In these sessions, students used the system as an extra-curricular learning activity for mathematics, natural science and social science. Prior to interacting with the system an orientation session on the features and operating procedures of QPPA was arranged for all participating students.

Measurement Instruments

A post-session self-report questionnaire was disseminated to students to be completed individually. The questionnaire consisted two parts. The first part measures student "Motivation toward the Learning Experience." Hung's "Learning Experience Scale" were adopted and adapted to make the items better fit the learning situation and target population involved (Hung, 2001). In total nine Likert scale items were included and rated on a five-part discrete scale, with corresponding verbal descriptions ranging from "strongly disagree" through "disagree," "no-opinion," "agree," to "strongly agree." To counteract possible response-set tendencies, both positive and negative statements were included. Sample questions included, "*After initial contact, I frequently thought of using the system again; the system grabbed my attention at first, but did not sustain my attention for long.*" The internal consistency reliability (coefficient alpha) for the scale was 0.70.

The second part of the questionnaire solicits student opinions on system's usability under different conditions. Three questions were included—(1) Constructing questions for which of the following subject matters (i.e., mathematics, natural science, social studies, etc.) is most difficult (mark only one), and in what way; (2) Constructing questions for which of the following subject matters is the easiest (mark only one), and in what way; (3) Your overall reaction and suggestions to the system.

Results on Student Motivation Toward the Learning Experience

After tallies on the negative statements on the scales were reversed, it was found that at an average 66.62% participants felt "agree" or "strongly agree" to statements on the motivation scale. Overall, students rated favorably on the system's motivational value. Student written responses to the open-ended question (i.e., your overall reaction and suggestions to the system) gives clues as to the system's motivational value to the users—"*Constructing questions gives me a sense of achievement; engaging in this kind of learning activity is fun and helps me learn along the way; I hope more subjects can adopt the system to support learning; I like the system because it helps me think more critically; by constructing and assessing questions, I can help others learn better; quizzing each other via the system is fun, exciting and less threatening; I can challenge other's thinking and reasoning; ranking lists make learning more rewarding and satisfying; a larger chance of winning is provided via the various kinds of ranking lists available,* etc."

Analysis of the aforementioned statements suggested that the sources of motivation might be from a sense of achievement, pure entertainment, altruism, sense of security, challenging other's existing knowledge, feeling of satisfaction, and sense of confidence, etc. Via embedding an array of sources of motivation within the system to satisfy people various motivation, it seems that QPPA provides a motivational learning environment and experience for participants.

Results on the Use of the System For Different Content Areas

Data from student opinions on the system's usability under different conditions indicated that among mathematics, natural science, and social science, 55.8% students felt that constructing questions for mathematics was the most difficult one whereas 40.4% students thought constructing questions for natural science was the easiest one (See Table 1 for details). A one-group chi-squared test was followed to test statistical significance. Though it did not yield a statistically significant level of .05 for the easiest (chi-square = 1.529, df = 2, $p > .05$), a one-group chi-squared test showed a statistically significant difference for the most difficulty one (chi-square = 268.67, df = 2. $p < .0005$).

Different Subjects	The Easiest	Most Difficult
	N (%)	N (%)
Mathematics	14 (26.9%)	29 (55.8%)
Natural Science	21 (40.4%)	6 (11.5%)
Social Science	16 (30.8%)	15 (28.8%)
Total	51 (98.1%)	50 (96.2%)

Table 1: Student Opinion Toward Usability of QPPA for Different Subjects

Constant comparative method was used on the 82 entries from student written responses to the two open-ended questions to provide explanations for the observed phenomenon (i.e., using QPPA for which of the following subject matters is most difficult and in what way; using QPPA for which of the following subject matters is the easiest and in what way). Based on the data analysis, it indicated that several factors influencing the learning activity, especially multiple-choice items development. These include: typing skills and speed, availability of instructional materials and supplementary learning resources, availability of sample test items, individual capability in the subject matter, the complexity and difficulty of the subject matter, computer literacy, and Chinese phonics. For instance, students mentioned that *"Constructing questions for natural science is easiest because many references with sample test items available," "Constructing questions for math is most difficult partly because there are a lot of numbers and symbols involved, and mainly due to the fact that you need to completely understand the principle in the instructional materials," "Math is difficult and harder to apprehend, comparing to other subjects," "Posing arithmetic story problems is hard," "I am good at natural science," "It is hard to come up with plausible options for social science content, and usually there are a lot of typing involved,"* etc.

Conclusions

With the advent of networking and multimedia technologies, the emphasis on technology-based education of all kinds for the support of student learning has been the focus of contemporary education. In the present study a networked system enabling students to contribute to multiplo-choice item development, which, in turns, are evaluated, viewed and practiced, was launched in 2001. Via containing different sources of motivation as suggested by motivational theorists the system tended to cultivate a motivating learning environment for participants. Moreover, several factors influence the learning activity, especially item development. Based on the obtained data guidelines pertaining to instructional implementation were offered.

To support question-posing learning task, instructors might want to provide additional instructional scaffolding mechanism for different subject matters during the activity. Specifically, in additional to references and sample questions, orientation training sessions on question-posing strategies, such as, sentence analysis, use of exam clue words, model higher-level questions, base exercises on a hierarchy of comprehension levels, etc., as suggested by Balajthy (1984), may help question construction exercise more manageable and meaningful. Besides, tutorial sessions for special symbols key-in, for instance, operators for addition, subtraction, multiplication, division, equation, power, and fraction, etc. for mathematics, would be indispensable particularly for younger learners whose typing skills, computer skills and phonics for Chinese spelling capability is limited.

Abstract: The present study investigated the impacts of the anonymity feature of networked synchronized competition on students' continuing motivation and interpersonal relationship. Two classes of fourth-graders (N=68) participated in the study for three instructional sessions. A synchronous competitive gaming system was devised to have each pair of students compete answering multiple-choice questions with another randomly assigned pair of students. Data analyzed using independent samples t-test for each of the dependent variables yielded that there is a significant difference between different treatment conditions in motivation ($p = .047$); however, no significant differences were found in student perceptions toward their opponents. In view of the preliminary nature of this study, future research in related areas to extend the scope and extent of the generalizability of the present study are proposed.

Introduction

Competition has been suggested as a means of enhancing the motivational appealness of educational activities, and as a way to foster learner involvement and excitement in the activity (Butler & Kedar, 1990; Malone & Lepper, 1987). Adding an element of competition between individuals or groups is widely believed to be a motivational-enrichment strategy in play, work, and education (Deci, Betley, Kahle, Abrams & Porac, 1981; Malone & Lepper, 1987). Despite the fact that competition is often considered as an effective technique to motivate people to learn and excel, the adversary effects that competition may have on learning have provoked discussion and concerns. While empirical bases suggest that competition may have detrimental effects on learning (Nicholls, 1983; Pepitone, 1980; Stipek, 1988), past studies were primarily conducted in traditional classrooms involving face-to-face situations. Anonymous real-time group competition and their associated effects were out of academic research arena till the advent of networking technologies. Gleaned from social-psychological research that anonymity leads to deindividuation; that is, individuals may act as if they are submerged in the group (Diener, Fraser, Beaman & Kelem, 1976; Gergen, Gergen & Barton, 1973). Though this line of research suggests that anonymity contributes to deindividuation, the effects of loss of identification within synchronized competitive learning environment have yet to be explored. Thus, the present study set out to examine the effects of the anonymity feature of computerized synchronized team competition on some of the educational outcomes that have caused concerns among educators and researchers in the past, that is, competition's effects on students' continuing motivation and interpersonal relationship among competing groups.

A number of questions can be examined within this context. First, will the added feature of anonymity enhance students' continuing motivation toward the computerized competitive educational activities? Malone and Lepper (1987) suggested that there are four primary sources of intrinsic motivation that an activity may provide an individual. The one that is most relevant to anonymity of opponents in competitive learning environments is the construct of challenge. Malone and Lepper (1987) suggested that the optimal challenging activity is one whose attainment is uncertain. As participants in the anonymity condition don't know whom they are competing with within the learning system, it introduces additional source of intrinsic motivation—challenge, due to uncertainty of success. Whether this added feature of anonymity in networked synchronized competition would enhance its motivational appealingness to participants via increasing uncertainty of success is examined in the study.

Second, nonverbal cues, such as gestures and facial expressions, are easily emitted in face-to-face situations. Will such emotions and/or reactions, which are more commonly aroused and detected in face-to-face team competition, for instance, uneasiness, impatience, aversion, resentfulness, and feeling of agitated, etc., contribute to more negative perceptions toward opponents, as compared to anonymity team competition? Or, conversely, anonymity has been shown in social psychological research to lead to deviant, harmful, and socially undesirable behaviors due to losses of sense of self-awareness and individual accountability (Festinger, Pepitone & Newcomb, 1952; Gergen, Gergen & Barton, 1973). Will such anti-social behaviors manifest themselves within anonymity competitive learning situations to an extent that lead to less favorable perceptions toward their opponents as compared to face-to-face team competition?

In sum, two research hypotheses are proposed.

1. There will be significant differences in student continuing motivation of the learning task between students assigned to the anonymity team competition condition and those assigned to the face-to-face team competition situation.

2. There will be significant differences in student interpersonal relationship between students assigned totwo different treatment conditions.

Methods

A total of 68 fourth-graders (ages 10-11) from one primary school in the southern part of Taiwan participated in the study. All students in the participating school had been taking computer literacy classes for almost two years, and possessed a fundamental krowledge of computer hardware and software operations.

A synchronous computerized competitive gaming system, calledJoyce, was devised for the purpose of the study. Joyce withits origin dated back from 1972, in essence, adopts a board-game format that allows learners practice answering multiple-choice questions with competing opponents simultaneously via network or in a face-to-face situation (Yu, Chang, Wang, Han, Chan & Liu, 2001).

To compare the differential effects of face-to-face and anonymous real-time team competition on student motivation and interpersonal relationships, two competition modes were derived in the study. In Treatment A (the face-to-face team competition condition), pairs of students competed with their randomly assigned opponents, who were sitting next to them for the duration of the activity. In Treatment B (the anonymity team competition condition), pairs of students also competed with their randomly assigned opponents. However, in Treatment B, competing teams did not know against whom in the class they are competing because pseudonyms instead of real names were used during the interaction. In Treatment B, pseudonyms were randomly selected from a list by each dyad and used to log in the system for the duration of the activity.

In the present study, students participated in three instructional sessions for three consecutive weeks. In the first session, ground rules for participating in the activity, including "Be on time," "Stay in your seats," and "Raise hands before posting questions," and the purpose of the learning activity were announced and explained. Various features and the operating procedures of the learning environment were introduced and demonstrated before having students compete answering social science questions with their randomly assigned opponents. At the beginning of the second session, the ground rules and procedures for running Joycewere reviewed before having students compete answering natural science questions on the system with their randomly re-assigned opponents on computers. At the beginning the third session, before having pairs of students compete with their randomly re-assigned opponents on social science and natural science questions, the teacher quickly reviewed the basic procedures involved in operating Joyce. Students were given a questionnaire to be completed individually afterwards

A post-session self-report questionnaire was disseminated to students to be completed individually. The questionnaire consisted of two 5-point Likert scales. They are "Student Continuing Motivation Scale" and "Student Perceptions of Opponents Scale." Ten statements were included to test students' continuing motivation toward the learning task. Sample items included, "*I frequently think of playing the game after the first instructional session; I wish I can participate in this kind of activity again in the future, etc.*" 16 items with high evaluative content were included to test the hypothesis relevant to student perceptions of their opponents. Sample items included, "*My opponents are slow responders; My opponents make me nervous; Interacting with my opponents is an unpleasant learning experience for me, etc.*"

Results & Discussion

The means and standard deviation (SD) values for each of the dependent variables are listed in Table 1. The results showed that students in the anonymity condition tended to have higher mean scores than those in the face-to-face team competition condition on both of the sub-scales.

	Face-to-Face Team Competition (N=34) M, SD	Anonymous Team Competition (N=34) M, SD
Motivation	40.2647, 8.6701	43.9706, 6.2401
Perceptual Impressions of Opponents	54.2647, 11.0736	57.5000, 9.6836

Table 1: Descriptive Statistics of Face-to-Face vs. Anonymous Team Competition on Interpersonal Relationship and Motivation

Collected data were analyzed using independent samples t-test on each of the dependent variables. Results from t-test showed that there is a statistically significant difference between the two treatment conditions in student motivation, t (1, 66) =2.023, p = .047. However, data analysis did not show statistically significant differences between the two treatment conditions in student perceptual impressions of their opponents, t (1, 66) = 1.282, p = .204. The obtained results of the two treatment conditions on each of the dependent variables are discussed separately in the following sections.

Motivation

Based on Malone & Lepper's theory on intrinsic motivation, the present study conjectured that adding the feature of anonymity might increase the intrinsic motivational value of the competitive learning activity via increasing its challenge level originating from uncertainty of success. The results of the present study provided empirical evidence supporting our hypothesis that suppressing opponent's identify during synchronized computerized team competition promotes students' continuing motivation of the learning task. Students in the anonymity condition tended to be more willingly to engage in similar kinds of learning activities in the future as compared to the face-to-face condition. Anonymity condition in the study seemed to be more facilitative of continuing motivation due to the added ingredient of uncertainty of success and the fun and suspense of not knowing who the opponent is while participating in the activity.

Interpersonal Relationship

Though students in the face-to-face team competition rated their opponents less favorable than those in the anonymity condition in the present study, the obtained data, however, did not yield statistically significant differential effects in subject perceptions toward their competitors. Observations during the experiment indicated that by engaging actively in the gaming system, which is filled with numerous intrinsic motivating features, students in neither face-to-face nor anonymous competitive learning situations displayed the kind of defensive or aggressive behaviors toward their opponents as warned by social psychological or mass communications researchers. As no aversive behaviors directed at opponents were exhibited during the interaction, it did not have a negative effect on interpersonal relationship.

Conclusions

The present study set out to examine the feature of anonymity within a computerized competitive learning environment on students' motivation and interpersonal relationship. The obtained datafrom the present study tended to lean toward the position that to enhance students' continuing motivation of the learning task networked team competition where opponents were not identified (i.e., anonymous) might be a more preferable instructional strategy to adopt, rather than a face-to-face team competition approach. In view of the preliminary nature of the present study, it is tentative at best to recommend that designers of competitive game-based learning systems include the feature of anonymity in their system to support student learning.

It is clear that much more research in this area is needed to extend the scope and extent of the generalizability of present study. As the present study employed fourth-graders who were engaging in multiple-choice questions answering activity for three instructional sessions, future studies with longer duration of experimental time, different age groups, and interaction tasks should be research priority. Moreover, the present study involved pairs of dyads competing in objective-type question-answering practice. As group process in larger group sizes are more complex than dyadic ones while engaged in problem-solving questions, further studies involving team competition of various group size and different question types might make finer distinction so as to make practical recommendations regarding the particular situations in which anonymity could be used for the enhancement of learning outcomes.

Abstract

To cope with the increasing demand on educational opportunities in web-based educational environment, various intelligent tutoring systems are developed. These tutoring systems engage the students in learning by doing. To make the systems even more beneficial and adaptive to the student needs. This paper presents the neural network model for Web-based adaptive learning. The developing model is based on hierarchical mixtures of experts for regression and classification. Courses are adapted to students by taking into account their own features(such as background knowledge of the learner) along with the actions performed by them during the learning process. The proposed approach allows generating the content of a hypermedia page from pieces of educational material based on a goal-oriented way of teaching. We show a possible solution, which we have used for course of the primary school about computer education. We then discuss this solution as well as advantages and problems, and identify several research issues, which have still to be solved for adapting course materials

Keywords

Adaptive hypermedia, Parallel Mean Field Annealing, Hierarchical Mixtures of Experts, Electronic-Textbook, Intelligent Tutoring System

1. Introduction

Recently, hypermedia systems have become more and more popular as tools for user driven access to information. Hypermedia systems used for learning generally offer no constraint on the user. Proponents of hypermedia argue that a student should able to learning using methods that suit them. Adaptive hypermedia systems engage a larger number of interactions without the help of an adapter to change their state or behaviors. An important characteristic of an adaptive hypermedia system in order to succeed to its educational potential is the opportunities it offers for individualized learning.

The introduction of adaptivity into the hypermedia systems aims at providing the system with the ability to change dynamically according to the changing learner's needs and learning level[3,4]. It would be very helpful to have different contents for different types of learners, for students with different interests and

---

This study was granted by the research project the Jeonju National University of Education

different initial knowledge on the topic. To make a step in this direction, we propose a neural network approach to implement different contents and contents sequencing. Also, we propose realization of an adaptation component for an open, adaptive hypermedia system, which, on the other hand, enables integration, and adaptation of learning material found in the WWW. The proposed model is useful in dealing with the problem of extracting information about the students.

2. Approache to implement adaptivity in educational hypermedia

Our aims are to facilitate hypermedia systems with ability to adapt to their students' needs as they progress through the systems. To this end we have developed a prototype hypermedia shell, which provides a combination of knowledge-based representations and an extended hierarchical mixtures of experts(eHME) approach. Figure 1 demonstrates the architecture of the proposed approach.

Figure 1. Approach of the adaptive educational hypermedia

The structure of the knowledge domain is represented as a bayesian network of domain concepts. In this paper, we focused on the adaptive learning presentation approach, which is usually realized using eHME. We construct dependency graph for the knowledge items that describe the computer literacy education in the Primary school. The dependency graph is the neighboring graph of the partial ordering < of the set of knowledge items. The proposed network is as figure 2. The domain knowledge structure is based on a concept level hierarchy where all the concepts are identical and are the connected with prerequisite relations. Each concept takes values from 0 to 1.0. It consists of a series of expert networks, which are trained on different parts of the educational materials (text, multimedia data, etc). The first layer is organized in classes, such as text, multimedia date, examples, simulations, exercises and so on. Weights connecting the internal layer and the final layer are connected to several classes of educational material. The educational material is then joined under a predefined form of presentation to generate a course. The output of the experts are combined by a gating network which is trained to stochastically select the expert which is performing best at solving a particular part of the problem.

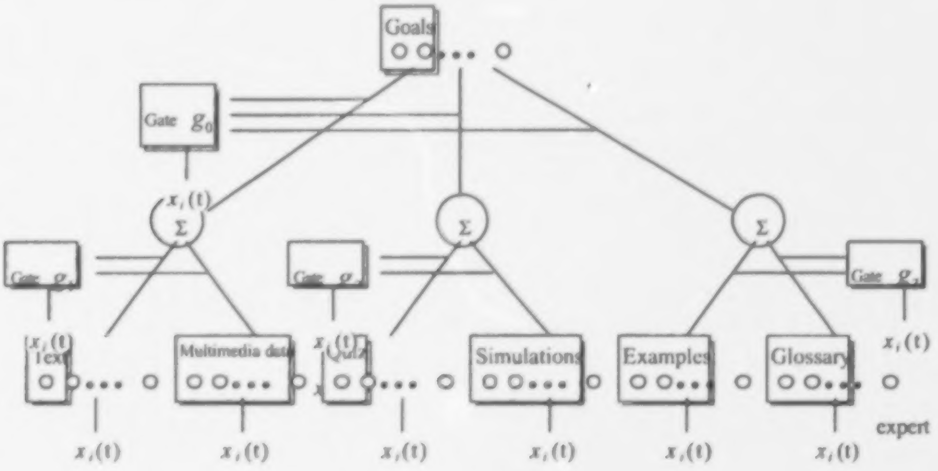

Figure 2: The structure of an eHME of the domain

Expert network(i,j) produces an output $\mu_{ij} = f(\theta_{ij}x)$, where θ_{ij} is a weight matrix and f is a softmax activation function. The gating networks also have a softmax output activation function. The top level gating network is the softmax function. The architecture operated synchronously: (a) it updated the stated of nodes simultaneously, and (b) all the nodes have the same input patterns during each iteration cycle. Patterns of relationships among internal layers implement different strategies of generating the content of the selected knowledge goal. The values of concepts are changed through the learning process as follows. The proposed network is trained using the modified EM algorithm. This algorithm consists of two steps: a propagation of posterior credits to each node in the model (the E step) and a maximization of a likelihood function weighted by the posterior credit of each node (the M step). Details of the EM algorithm can be founded in [1,2,8]. In this section, we describe the extended EM algorithm with annealing forthe proposed network. The proposed annealing algorithm is called parallel mean field annealing(PMFA). This annealing algorithm is modified mean field annealing. Mean Field Annealing(MFA) algorithm deals with binary discrete spaces.

The SA(simulated annealing) and PMFA algorithm are present to solve the M-step of the EM algorithm. One of the two algorithms, PMFA algorithm has not yet used by others for the prediction problems. The conventional mean field annealing algorithm deals with the binary, multiple state problems, and so that algorithm is not appropriate to apply to continuous state problems. The proposed PMFA algorithm can be applied to continuous state problems. It was successfully applied to solving the difficult optimization problem [5,6]. The proposed algorithm can be founded in [7]

3. Conclusion

The use of eHME approach to facilitate adaptation to the students in the learning process in an adaptive hypermedia system is a novel approach. The project is currently in its early stages. The results of experiment can be improved on learner's learning process by matching the lesson to their level of understanding and educational needs. We currently investigate techniques to enhance the generalization performance of our approach.

ABSTRACT

The paper is to open Prof. Luc Duhamel's eTEXTBOOK in big multimedia classroom;
It is to show the multimedia application in teaching of UNIVERSITÉ DE MONTRÉAL;
It is to explore a future to educational multimedia…

INTRODUCTION

YU SISTERS MULTIMEDIA STUDIO started to design and produce the interactive multimedia teaching coursewares for Prof. Luc Duhamel from December, 2001 to April, 2002 so that professor can submit his textbook to huge screen for 280 students in the 350 seats classroom by computer and multimedia projector, meantime, created the online course for professor and his students to interactive eLearning website and to explore a new way to success by Multimedia Assisted Instruction - CDNet = CDROM + WEBSITE. (CDNet is a combination of educational software CDROM and eLearning website)

RESEARCH & DEVELOPMENT

Prof. Luc Duhamel proposed to practise the interactive multimedia coursewares in order to improve classroom teaching, YU SISTERS MULTIMEDIA STUDIO assisted Prof. Luc Duhamel to co-research and develop the offline and online course project.

POL1008 - FORCES ET COMPORTEMENTS POLITIQUES is one general theory course of political science and the students come from different departments and programs that have been spread during the last decade and the number of students is increased significantly at least in social sciences. Furthermore, the students of the course have more and more different backgrounds. With such disparate group of students it has become harder for the professor to teach. How to overcome all these problems related to the first year course? Multimedia is improving the big classroom teaching. Another advantage to use multimedia is that we can produce CDROM for the students (instead of books). CDROM give the opportunity to make update every year. How to make the 280 freshmen understand basic and abstract concepts very well and refresh their memories? It is one great challenge to Today's teaching and learning.

YU SISTERS MULTIMEDIA STUDIO designed the interactive multimedia presentation for teacher's teaching and the online course website for student's learning. The coursewares are compiled by text, image, audio & video, animation, when we designed the topic "Medias & Political Science", we decided to link the CNN's webcast program"911-Attack at USA" to show the power of media, and unforgettable moment on the Internet, however, even though we tried many times, but when we clicked the video clip for the 280 students in class, we found the download speed by LAN cable web was still very slow, because of the tech limitation, "the world shock" lost its impact. The problem let us to consider how to guarantee quality and real-time effects in class? How to effectively use and develop the external website and internal website (WebCT)for teaching and learning? At first, we put the offline PowerPoint coursewares to external website http://www.yusisters.com/luc.htm so that students could review the course and get the useful info out of class. WebCT is the world's leading elearning system, it is an internal website, only the course instructor and his students could use it with passwords.

Some promoted info needs to be searched by search engine, some detailed coursewares need to be locked by WebCT, but how to take advance of the external website and internal website for learning? How to design offline and online coursewares for teaching? How to get the solutions? We are studying and practising. But the educational multimedia application in the university has helped Prof. Luc Duhamel's one blind girl-student, the handicapped student got the good points in the exam through multimedia courseware assisted instruction.

In the 2002 winter term we finished the title"FORCES ET COMPORTEMENTS POLITIQUES"(9 coursewares) and practised every courseware in multimedia classroom, 280 students from different departments evaluated the experiment and Prof. Luc Duhamel got the excited feedback and inspiration. Now let us focus on one courseware "MEDIAS & POLITICAL SCIENCE", because it is a new exploration in educational multimedia.

How to clearly show the relationship of Medias and Political Science to students?

YU SISTERS MULTIMEDIA STUDIO designed and produced the new radio program in French to broadcast "RADIO ADDRESS OF THE PRESIDENT", this is the most famous radio program in the broadcasting history.

The 32nd American President (1933 - 1945) Franklin Delano Roosevelt hosted the radio program "Fireside Chat" delivered from the White House, he made the White House as a warm home and he sounded like a FATHER sat near fireside to gently chat with his family members to submit his political strategies to his beloved motherland and people. On World War II, when the Japan attacked on Pearl Harbour in December 1941, Roosevelt secured a declaration of war against Japan with a stirring speech. In April of 1945, the president collapsed and died of a cerebral haemorrhage, just weeks before the German surrender...

The above is the best example that one president took advantage of mass media to broadcast his political ideas and policies from 1933 to 1944 by the radio program "Fireside Chat".

On Sept. 11, 2001 when terrorists suddenly attacked at USA, it was a world shock! The American President Bush hosted his television program in the CNN evening news

Good evening.

The pictures of airplanes flying into buildings, fires burning, huge structures collapsing, have filled us with disbelief, terrible sadness and a quiet, unyielding anger.

These acts of mass murder were intended to frighten our nation into chaos and retreat. But they have failed. Our country is strong. A great people have been moved to defend a great nation...

President Bush's television speech won the supports all over the country and around the world; America started its new war against terror.

Because UNIVERSITÉ DE MONTRÉAL is a French-speaking university, the produced radio and TV programs from USA need to be translated into French and to be re-produced according to the instructor's course content. Because CANADA is a bilingual country, the website's design is required to have the 2 v ersions: French & English so that YU SISTERS MULTIMEDIA STUDIO has to think of more works and problems in the future.

FUTURE

Etraffic Solutions Inc. & SIDES Online reported:

The Educational Multimedia:
- **2002: All teachers to be equipped and skilled in the use of the Internet & multimedia**
- **2003: All students to be digitally literate by the time they leave school**

The Education Market:
- **2025: 180 million learners globally**
- **2025: 30 – 80 million will be online**

The Issues & the Opportunities
- **Lack of quality educational content to date has deterred teachers and students (OECD)**
- **Inadequate professional development for teachers and administrators (Kerrey Report 2000)**
- **Lack of good content in online resources (OECD)**
- **Lack of interactive multimedia in online resources (OECD)**

The eLearning Market Services and Products
- **equipment, local networking, install, set-up, servicing**
- **Internet access**
- **operational software**
- **content: multimedia software, Internet applications, web applications**
- **technical support and training**

CONCLUSION

Prof. Luc Duhamel from UNIVERSITÉ DE MONTRÉAL collaborated with YU SISTERS MULTIMEDIA STUDIIO for multimedia courseware research and development, it is a start and trial.

UNIVERSITÉ DE MONTRÉAL has developed eLibrary (http://www.bib.umontreal.ca/) and open the world's leading elearning system - WebCT(http://www.coursenligne.umontreal.ca/) to all the teachers and students, over 500 courses have been created on WebCT since 1999. The web-based learning resource "eLibrary" and the web-based coursesupport system "WebCT" as well as the equipped multimedia classrooms in the UNIVERSITÉ DE MONTRÉAL are ready, but how to use them by all the teachers and students? The technical training will be a must. How to create the interactive multimedia courseware, design user interface and software for teaching?

YU SISTERS MULTIMEDIA STUDIO is exploring the offline teaching and online learning to higher education: to create CDROM for intelligent computer-assisted instruction in multimedia classrooms and to build the virtual universities websites for interactive distance education..

Welcome to Montreal - the international multimedia capital

Welcome to Multimedia city in downt own Montreal, Canada

Handheld Computing in Education

Abstract: Handhelds or Personal Digital Assistants (PDAs) may just become the mobile computing technology that revolutionizes the face of learning. The intuitive interface, portability, and wealth of third-party software applications make the handheld an ideal educational tool to enhance instruction and learning in and out of the classroom. Educators are exploring ways in which the handheld computer can improve active learning in the classroom, and also provide students with valuable insights into real-world applications of handheld technology.

Introduction

Computers can be great learning tools when used effectively, but high costs have long hindered educators from providing each student with a desktop computer or laptop of their own. Some educators indicated that computers have not have a positive impact on teaching and learning because students and teachers have limited access to them and thus are not using them (Soloway et. al, 2001). Many educators have been exploring the less-expensive handheld option. Already common in the business world, handhelds or Personal Digital Assistants (PDAs) are just now being introduced into schools, with iPAQs by Compaq Computer Corporation, Jornadas by Hewlett-Packard Company, Palms by Palm Inc., and Visors by Handspring Inc. competing for the education turf. Today, handheld devices such as Palms and Pocket PCs are making technology accessible, affordable, and fun for teachers and students alike. More and more school officials believe that handheld computers, which are relatively inexpensive compared with laptops or desktop computers, are the best way to put a computer in the hands of each student. This is an important equity issue because handheld computing brings together the power of technology with the ease, convenience, and low cost of small portable devices, thereby offering a solution to access and equity issues.

Using Handhelds in Education

Handheld technologies are changing the way people access and work with information. These devices are becoming smaller, cheaper, better, and more connected. Educators are exploring ways to take advantage of these emerging technologies to encourage exploration, stimulate learning, and enhance lifelong learning. Handhelds give students full-time access to computation and wireless connectivity, while expanding where educational computing can take place to the home, field, and any places. Handhelds also could be used to assist students with special needs such as dyslexic and physically handicapped students.

Handheld devices function not only as a computer, but also as a textbook, media, calculator, calendar, notepad, and pencil. Students can use the devices to edit and revise their work. Handhelds also hold advantages over traditional computers with their ability to beam data from one device to another (Branigan, 2001). The infrared beaming capability offers opportunities for real-time student collaboration and allows users to "beam" word processing documents, spreadsheets, drawings, data, and even applications to each other without having to download and print out or send via e-mail. Students can beam questions and assignments to teachers or send parts of a project from their own handheld to other classmates.

Handhelds offer portability while at the same time packing enough computing power for writing, calculation, graphing data, data gathering and manipulation. They also can send and receive e-mail, access the Web, through a desktop, their own modem or wireless device. Some can even record your voice, play videos, display digital photos, drawings, or hold maps, city guides, or an electronic book.

Students can use handheld devices to gather, store, and retrieve important information. They can use handhelds to monitor their grades and keep track of their assignments and due dates. Students armed with a handheld can also take advantage of the plethora of software options including dictionaries, e-books, graphing calculators and more.

Handhelds offer simple, quick, inexpensive ways to communicate, teach and learn wherever you go. With a handheld, a teacher, student or administrator can take notes, calculate, sketch ideas, access the Internet wirelessly, collect data, access resources, manage school activities and courses and instantly beam information to others. Teachers and administrators can give PowerPoint presentations right from a handheld with the Presenter-to-Go module connected directly to a digital projector. Teachers can use handheld computers for personal management tasks and for teaming with others. They can share information and collaborate with administrators, other teachers, and students. In addition to the general applications for personal management, there are many educational applications for using handhelds in teaching and learning: course management, content delivery, assessment, communications, calculation, and research.

Advantages

Handhelds provide a feeling of true ownership. Although students can use computer lab or classroom desktop computers, they must share them with others. A handheld computer, on the other hand, can be a true "personal computer." Like desktop computers, handhelds can be transformed by adding different software or hardware. They can be used as scientific graphing calculators, digital cameras, notepads, cell phones, digital voice recorders, or scientific sensing devices. Their small size makes them easy to carry from class to class and from school to home, giving handhelds a major advantage over the desktop computers and laptops. This portability, combined with powerful data processing and versatility, makes handheld computers a significant educational tool. Many educators believe handheld computers will transform educational technology in schools. For as low as $100 each, students can have more computational power in the palms of their hands than ever. Handhelds offer more versatility than desktop computers and are much more portable than the laptop. In addition, many of the newest handheld models can be wirelessly networked, students can send and receive e-mail and surf the Web without having to "sync up" to a personal computer.

Problems

Despite the potentials of handhelds in education, some school districts see the problems of using handhelds in the classrooms. The handhelds are not universally enamored by educators. Among the major concerns are the theft risk, high cost, and the distraction resulting from the misuse by students. Handhelds can be a threat to classroom order and student integrity. Some schools have banned their use because some students use the handhelds to cheat on tests, play noneducational games, or e-mail friends inside or outside the school (Shields & Poftak, 2002). In addition, current handheld devices have many limitations: the computational power tends to be low, multimedia is problematic, writing extended documents via stylus-input is inefficient, and the screen is too small.

Conclusions

Today, handhelds such as Palms and Pocket PCs are making technology accessible, affordable, and fun for teachers and students alike. Handheld computers may just become the mobile computing technology that revolutionizes the face of learning. The intuitive interface, portability, and wealth of third-party software applications make the handhelds an ideal educational tool to enhance instruction and learning in and out of the classroom. Educators are exploring ways in which the handheld can improve active learning in the classroom, and also provide students with valuable insights into real-world applications of handheld technology. Handhelds give students full-time access to computation and wireless connectivity, while expanding where educational computing can take place to the home, field, and any places.

Abstract: This paper describes the pilot *Museum Satellites* project, involving development of a web-based learning activity, linked to a museum. The objective of the project is to improve the learning experience that takes place in museums by providing pre and post visit continuity for museum visits and opportunities for a more personal and meaningful learning experience. *Museum Satellites* are activities for multimedia exploration, visual organization of multimedia information, and presentation. The project explores the possibilities of spatial organization of information for inquiry, reflection, presentation, and collaboration. The satellite becomes available on the web for asynchronous collaboration of multiple participants, making it an ongoing exhibit. As part of the museum's educational outreach, the satellites belong to the museum, which makes its resources available by providing images of their artifacts, information sources, and guidance of its educators and experts.

Introduction

Together with museums' missions of object preservation and research, museums aim to teach their cultural patrimonies. This historical mission has been changing over time and in accordance with education theories and the technologies that are available. This project involves software for enhancing the learning experiences of museum visits and improving the general teaching possibilities inherent in museums and their educational outreach.

A Museum Satellite is a web-based program that allows for a participant or group of participants to create a multimedia visual organization of the exploration of a topic, question, or object related to the Museum's themes and collections. This visual presentation of their inquiry will work as a tool for thinking and organizing the search, as well as for sharing their ideas with others. These multimedia maps will allow experts and educators from the museum to make suggestions and relations to ideas and objects, helping the participants to create more domain expert-like associations.

Rationale

Experience in different museums has shown a need for a means of making school and individual visits to museums a less isolated experience. Museum visitors who take full advantage of the visit experience are those who bring authentic questions with them to the visit. These questions can have their origin in school activities and projects or they can emerge from students' own curiosity and inquiries (*Foundations*, 2000). These questions are the basis of scientific research and artistic development that are sometimes ignored by the educational system. Helping the visitors' place this experience within the larger and more meaningful context of their personal questionings and providing means for exploring those questions after the visit is over can enhance the educational experiences that the museum provides to its visitors. The activities of inquiring and building representations help learners develop their understanding and therefore enhance the possibilities for attention and memory that foster understanding and interest during the visit. The Museum Satellite project involves learners in the development of spatial visualization and organization of information as a powerful tool for thought (Tufte, 1991). The process of organizing, demonstrating, and displaying ideas and conceptions is an understanding performance (Perkins, 1992) that allows learners to have agency in the construction of these knowledge representations and involves them in demonstrating their work.

As a pre and post visit activity, the Satellite provides a structure for using the visit to the museum as a resource and also as an avenue for further exploration of what was learned. The experience of working on constructing a Satellite will provide training for the learners in inquiry, helping them to define their interests and, possibly, even help them to figure out career paths.

Existing web-based activities offered by museums focus on giving access to digital images of the collections, lesson plans, and game-like activities. But they do not take advantage of new media and museum resources for learners to construct their own thematic research and exhibiting project. Different from what museums generally offer, this project provides the participants with a way to set up questions, ideas, resources, relations, and assumptions. The ability to visually display questions and ideas will help the learners start to explore the topic and develop critical thinking skills before the visit --as knowledge owned, during the visit, and, with the improvements of multiple modifications, developments, and collaboration of others, after the visit. Possibilities will open also for those students who cannot actually attend the museum but can collaborate with their classmates who do go to the museum.

This project is innovative in offering tools for helping students to organize their ideas and intellectual inquiries, visualize relationships, and link their work as an in-progress satellite to the museum website. By being part of the museum instead of the school, students can go on working on their projects beyond the school year. The Museums Satellites can work as an entry for using and exploring the museum as a resource for studying that can be accessed anytime, instead of a once a life school outing.

Project Description

Museum Satellites are multimedia web-based spaces which function as part of the museums educational outreach program for students or other interested visitors. They are spatially organized/displayed in-progress research maps with embedded annotation and discussion tools. Guidelines and tools are provided for the students to build their work areas and options include using images of museum artifacts as starting points, or using questions to start the inquiry. The satellites are supervised by museum educators who may intervene when they consider it appropriate, providing suggestions, questions, links, information for contacting experts, and so on. Museum resources for information and direct contact with experts of the specific topic of the satellite are integral to the success of the projects.

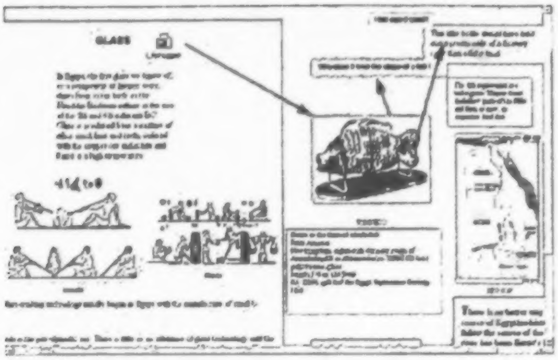

Figure 1: Example of a Museum Satellite work that has an artifact (a glass fish-shaped bottle) from Ancient Egypt as its starting point

Even though the satellites have starter authors, at some point they become open to the general public to participate in the discussions. In this sense, Museum Satellites are dynamic and will go on developing with time and increased interventions. As complementary to museum visits, they work as a pre-visit inquiry project that will elicit interesting questions and purposes to be brought into the visit and where to go on developing the knowledge and ideas gained from the museum visit. The satellites provide a way to keep in touch with the museum and become part of it as a contributor.

This pilot project will be developed for an art museum and will be started by high school students.

Future Directions

There are numerous possibilities for Museum Satellites as a multimedia technology that fosters and promotes the educational outreach of museums. In the near future we hope to establish a museum partnership, build the technology and space on a museum website from which the satellites will be linked, develop the human resources (probably interns) for its functioning, and advertise the project, in its pilot stage, with the teachers and schools that already have a relationship with that museum. This project can be exported and expanded by developing in multiple museums and by allowing the satellites to link more than one museum according to learning goals, academic research, and personal/institutional interest.

ABSTRACT

Nowadays wherever we go most of the people keep talking about information technology. One of the field that grows rapidly is E-Learning, which is another alternatives to enhance and deliver the contents. It is undeniable that the use of the latest technology today can help and simplify certain process. This paper will explain and elaborate about the method that applied in teaching 3d animation subject. This subject has been introduced since 1997 by Faculty of Creative Multimedia. The application of non-linear teaching does not mean to totally replace the current conventional way (actual class lecture). By having this method students can use their computer as vistual teacher and this method is just another enhancement for what already done. Finally we will expose and observe how effective is this approach in assisting virtual class.

KEYWORDS
Non-Linear, E-Learning, Interactivity, Three dimensional (3D) computer modelling,

1. INTRODUCTION

3D Computer modelling is apart of the process in creating 3D animation. At Faculty of Creative Multimedia this subject has been taught as an introductory course for 3D digital contents creation. This subject will allow student to cover various methods and techniques ranging from modelling, texturing, lighting and rendering. Back in 1997 this subject has been taught in a very conventional way with teaching aids like audio visual projection and power point presentation. The course assesment are based on quizzes, projects basis and exam. This subject is mainly a pre-requisite subject which the students need to accomplish before they can proceed to the major course like BSc. in Film Animation. Generally this course is delivered through theory, graphics and practical, hence we believe the old conventional is not enough to make it more interesting and understandable. Figures below explain about two methods used to deliever the contents.

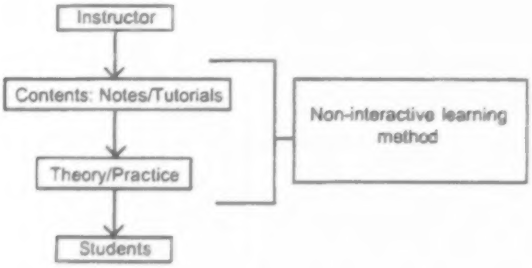

Figure 1: A conventional method for teaching 3D computer modelling

Contents: Notes/Tutorials
interactive web contents/ animated instructional video
Theory/Practice
Students
Interactive learning method

Figure 2: Non-Linear Web Based (NLWB) method for teaching 3D computer modelling

Basically both methods use a specific network backbone as its pipeline to transfer data from server. The students can access the notes from anywhere as long as they are connected to the internet. Furthermore, web based learning can give more unique opportunities to assist students in learning. Naps et al. [1]. discuss several particular advantages to using the web as a medium for delivering interactive material. These include remote accessibility to materials, support for disntance learning, the development of system independent applications and the use of hypermedia.As for NLWB method it has been enhanced with interactive video as their instructor, means students can repeatedly replay the contents for how many times they like which is impossible for the conventional method because it relies on physical instructor. We believe that presenting material in an interactive manner is an effective

BEST COPY AVAILABLE

technique for making learning more memorable. The major difference between these two methods is an additional of virtual instructor in form of animation has been added for the second method. Wetzel et al. [2] explain, "a variety of characteristics that make animations uniquely effective for instruction."After its implementation we found that this method is more efficient. Hiltz and Turoff[3]described, "*the uses of networked computer communications as a way of widening educational access and supporting life-long learning*". In the next page we will describe some basic introductions to the terms of interactivity and how NLWB system works as contents provider.

2. INTERACTIVITY

Interactivity can be divided into many levels which is ranging from click interaction, click, drag and drop and application of information in new and authentic contexts. In delivering the contents we will describe about five teaching architectures.Teaching architectures is a model that have been developed by Schank and Cleary [4], this is particularly related to computer implementation.

2.1 Simulation-based Learning by Doing

Humans learn by doing. Learning a new skill, then, would ideally include practice with the actual skill, accompanied by coaching, advice, and correction by an expert. The very nature of simulations requires active participation y the learner, who may sometimes 'enter in' to the simulated world as an actual participant.

2.2 Incidental Learning

Much information to be learned is not inherently interesting (think of the multiplication tables). Lists and facts are learned naturally, however, by engaging in fun tasks whose outcomes are interesting. In this design the base facts are imparted almost covertly.

2.3 Learning by Reflection

This strategy is appropriate when learners need to ask questions about their learning or need someone off whom to 'bounce' their ideas. In this case, the instructor (who could be virtual) helps the learner analyze the problem and find ways to continue in their progress.

2.4 Case-based Teaching

Imparting information at the precise moment of need has been recently dubbed just-in-time learning. In this architecture, learners may consult an expert when experiencing difficulties or out of curiosity. Experts, by virtue of their expertise in a field, have a large repository of stories to tell, or cases, which illustrate key learning elements relevant to the task at hand.

2.5 Learning by Exploring

When learners become involved in their new tasks, they naturally generate questions. These questions are optimally answered at the time they are generated. The key to this architecture is conversation, either virtually or in face-to face interaction. To elaborate interactivity in details, seven different forms of interactivity were derived from the taxonomies of interactivity [5] as illustrated in table below. (Table 1).

Interactivity	Description
Exploratory	Where the participant is exploring the "information landscape" for details of application structure and operation.
Navigational	Where the participant chooses to move from one location to another or selects a menu option
Presentational	Where the participant is watching the dynamic presentation of material
Involved	Where the participant is purposefully involved in following a set of actions to achieve a goal or assessing the static content being displayed
Manipulative	Where the participant is actively manipulating content objects to achieve a goal
Reflective	Where the participant is discussing aspects of their overall experience with the observer
Accidental	Where the participant initiates an interaction for which there is no program response

Table 1: Interaction Types

3. NLWB FOR 3D COMPUTER MODELLING

Due to the proliferation of the World Wide Web (Web) in recent years, many educators seek to improve the effectiveness of their instruction by providing web based course contents to the students. Motivated by this goal, we developed NLWB method to improve the current method. The next figure is a schematic that indicates the functionality of NLWB systems. The main contents are delivered through a website as a delivery engine and it is categorised into few sections: Course outline,file upload-submission, projects, quizzes, grading and interactive video based instructions (Figure 3).To make it more interesting we developed a virtual host to describe a basic introduction about this online course. (Figure 4). In general most of the project submission of this subject will be in image file format like JPG and TGA. (Figure 5 & 6).

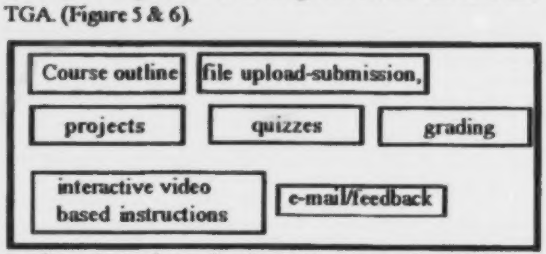

Figure 3: A schematic of NLWB contents for website

BEST COPY AVAILABLE

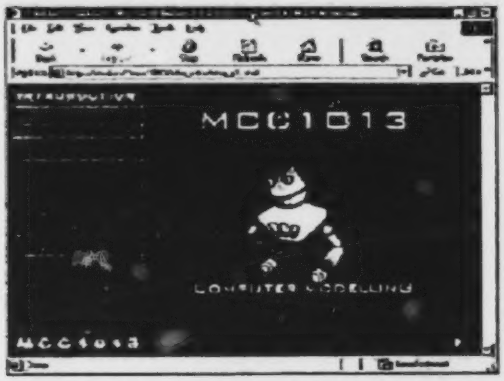

Figure 4: Main page of the website for 3D computer modelling subject.

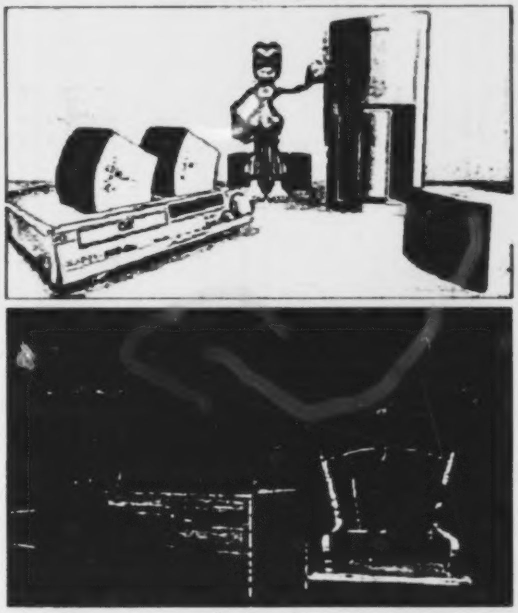

Figure 5: Examples from the project output (Image courtesy of FCM, MMU).

The next page we will discuss about the basic components/ elements in NLWB system for this subject. We will begin with the process for 3D computer modelling and followed by the infrastructure of the system.

3.1 3D Computer Modelling

For this subject the basic process will consist of modelling, texturing, lighting and rendering. Below we describe the process graphically. Firstly students may start their project by having some idea and from the idea, it will be transferred to the paper. Then it will be modelled in computer by using any 3D softwares. In our research we will concentrate on 3D StudioMax as a modelling platform. Modelling is a process of creating geometry in 3d software. It may involve with tweaking, sculpting and reshaping.(Figure 6).The following stage is mapping. This can be done by applying any mapping elements (texture/image) to the surface of the object. Balint [6], describes" *Image mapping is where an actual photograph or other raster image is applied to the surface of an object in order to give it a more realistic appearance. Texture mapping still affects what the surface of an object looks like, but deals mostly with mathematically generated shapes, colors and texture simulations.*"

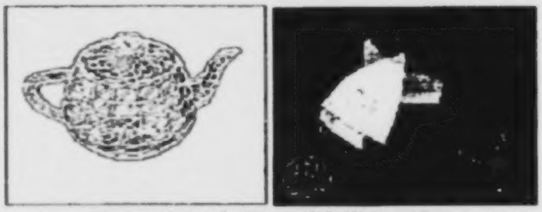

Figure 6: Basic 3D models that can be created by using any 3D softwares.

By adding texture mapping, we will basically get the look of the models as shown below. (Figure 7).

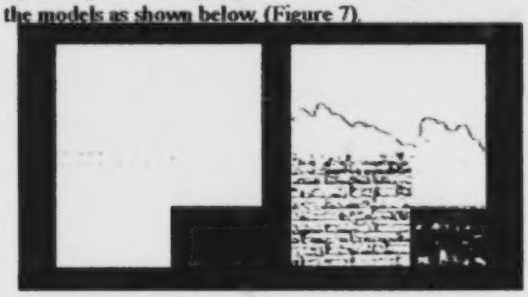

Figure 7: Applying texture to the 3d models.

Another important stage in 3D computer modelling is lighting. This method will make objects look more 3D effect. Lighting can be used to create more of a 3D effect by separating the foreground from the background, or it can merge the two to create a flat 2D effect. It can be used to set an emotional mood and to influence the viewer . Lights are one of the most essential parts to either having a great looking animation, or a terrible animation. They can be used to not only light up a scene, but to add depth,mood and visual effects. In almost any 3D scene, there should be a bare minimum of 3 lights. Finally we will discuss about the most crucial part which is rendering. Rendering is defined as when 3D software applies a skin to 3D geometry, which may involve coloring or even texturing the objects, but there are multiple types of rendering methods for different purposes. The next figure shows the rendering output in image format (Figure 8). For animation the output can be in sequence images or movie files.

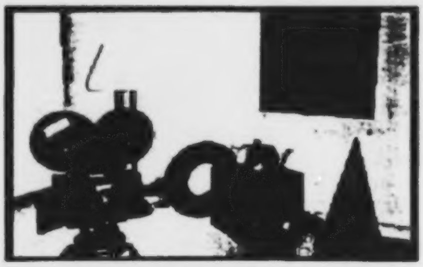

Figure 8: Fully rendered image.

The proper use of lights in computer graphics is one of the things that differentiates the talented artist from the

BEST COPY AVAILABLE

untalented. This is not a new topic as a large amount of work has been done on lighting issues in photography, film, and video.

3.2 Preparing Materials For NLWB

The contents for NLWB are driven by two aproaches; Video based (animated video) and Java Applet (Viewlet builder). Contents for both methods need to be prepared and provided by instructors. Once it is ready they will be transformed into these two types.(Figure 9)

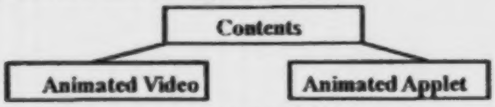

Figure 9: Contents divisions.

Animated video can be created by using video camera and transfer into any video format (mov,avi,mpeg). To optimise this, it must go for certain compression method, this is to ensure its practicality to be online. For second method (animated applet) it works as first method but as a series of sequence images, this means it is more economical and practical. For this purpose we use Viewlet Builder as its tool to create.(Figure 10).

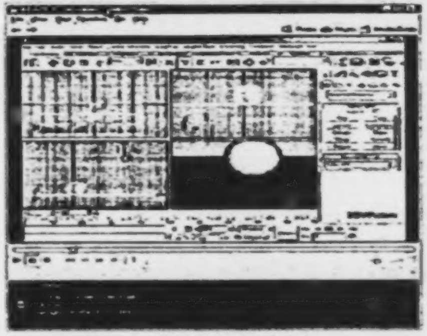

Figure 10: Animated video.

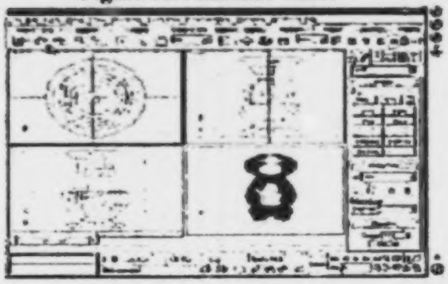

Figure 11: Animated applet.

All of these files will be uploaded to the server and it will be online for intranet use. In MMU the students can access their tutorials, demos and contents from internal server. It is illustrated as figure below. (Figure 12).

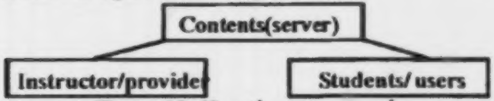

Figure 12: How the system works.

4. Research Findings

From the completed research, the authors concluded research findings into few points.

i-Animations allow an instructor to emphasize the important parts of a subject by removing unnecessary and distracting details. With the networked structure and support, this geographically help the student wherever they live.

ii-These methods have the ability to visually present subjects and ideas that would be difficult to illustrate in the real world. Students can save and re-use the contents outside of the campus.

iii-From the methods applied it can aid in discrimination by presenting cues that direct the viewer's attention to salient points of the presentation. Throughout the various animations presented herein, we have attempted to make use of these characteristics in order to make learning more effective.

iv-The contents only need to be prepared once, this means it will be stored as a set of database in the server and the instructor only need to update if necessary. Because of the large amount of time needed to develop quality materials, reusing existing materials as much as possible was a crucial objective.

5. Conclusions

The environment of online teaching/ virtual class is rapidly changing and contents development initiatives must respond appropriately. Currently the methods introduced in this paper are well implemented and may be for futher development a few things can be improved such as:

i-Network performance- due to more students rely on this method, the possible problem that may arise is net congestion. Thus, good network backbone is important.

ii-Developing a comprehensive understanding and contents of the interactive learning will not only lead to more effective usability and learning online environments, but also to those applications working better for the learner.

By presenting this paper, we hope this it goes some way to influencing and encouraging more institutions to do the same.

The Interactivity Issues in Using Blackboard

Chenfeng Zhang Ph.D.
Assistant Professor of Instructional Technology
Department of Curriculum and Instruction, Graduate College of Education
University of Massachusetts Boston
chenfengzhang@hotmail.com

The most difficult part in using Blackboard is the utilization of its interactivity functions to ensure a good interaction between the professor and students and among the students themselves. A surveyed of 10 faculty members from different departments in a Pennsylvania university was conducted to gather data on how they used the interactivity functions when they were teaching an online course. The survey revealed that most of the faculty members used asynchronous mode of interaction and seldom used synchronous modes of interaction. Suggestions are made to improve the interaction, especially synchronous mode of interaction.

Introduction

More and more university faculty members are using Blackboard for teaching an online course or as a supplement for their regular classes. From my own online teaching experience, I found that the most difficult part in using Blackboard is the utilization of its interactivity functions to ensure a good interaction between the professor and students and among the students themselves. There has been little research in this area. I surveyed 10 faculty members from different departments in a Pennsylvania university to gather data on how they used the interactivity functions when they were teaching an online course.

There are two kinds of interactivity abilities Blackboard offers. One is asynchronous, such as Email, Discussion Board and Digital Drop Box. The other is synchronous, such as the Virtual Classroom. From the survey we could see that the faculty members were using more asynchronous modes of interaction than synchronous modes.

Results of the Survey

The ten faculty members surveyed were from the Education Department, Math Department, Computer Department and Music Department. All of them were teaching one or more online courses at the end of the Spring semester 2002 when the survey was conducted. They had first-hand experience of using the interactivity functions of Blackboard.

The first set of questions was on the asynchronous mode of interaction, namely, the Email, Discussion Board and the Digital Drop Box. Eight faculty members used both the email capability in Blackboard and their own email account. Two faculty members only used their own email accounts. The reason for this was that personal email accounts were normally easier to use than having to log on the Blackboard server to access the email. Most of the faculty (80%) used email to respond to a quick individual question, to announce cancellation of a field trip and to send compliments to students after a test or exam. They used Announcement in Blackboard as a means for regular announcements. Only two faculty members used their own email accounts for regular announcements.

All the faculty members used Discussion Board. In a typical semester, they would post 8 to 20 discussion questions that students can discuss. Students were encouraged to express different opinion on another students post. 5 faculty members allocated 10% of the total grade for actively participating in the discussions. All the faculty members created a thread in the Discussion Board entitled "Help Each Other Section". They were doing so because another faculty members sent an email to his fellow colleagues to suggest that the "Help Each Other Section" was a very good idea to enhance interaction among the students. In this section, students could post whatever questions they had and sought answers from fellow students. Eighty percent of the faculty members would go to this section to monitor the progress, but did not participate in the answering of questions. Only two faculty members did answer students' questions in this section.

Most of the faculty members found using the Digital Drop Box a headache. Nine out ten of the faculty members used Digital Drop Box. Five of them only used it as a means to receive students' work or projects. The other four faculty members used Digital Drop Box to receive students' work and made comments on their work and sent it back to them. But almost all the faculty members using Digital Drop Box complained that it was troublesome to use. First, the server is slow. Second, they had to open up students' work in another software, made comments and saved the file before sending it out to the students. The Digital Drop Box was designed in a way that all the files were on the same page and it was difficult to tell if the file was sent by the student or sent by the professor.

The second set of questions was on the synchronous mode of interaction, namely the Virtual Classroom. The synchronous interactivity tools were not commonly used by the faculty members. Only two of them used the chat function for a couple of times. They found that when they used the chat function, students had to be present before the computer at a predetermined time and not all students could do it. Also, when several students were talking at the same time, it was difficult to follow up what each student tried to say. Easily, the chat would go uncontrolled. No faculty member had ever tried to use the White Board or the voice function in the Virtual Classroom. The main reason was that the faculty members themselves were threaten by the technology and had a hard time when they experimented with these functions. They were afraid that they would not use these functions properly in actual online teaching.

Most of the faculty members indicated that their major ways of interaction with the students were Discussion Board and Emails. As for ways to ensure interaction among students, most faculty members assigned group rather than individualized projects to encourage the interaction. One faculty member assigned heavy loads of work in order to force students to cooperate with one another to finish them.

From the survey we could see that most of the faculty members used asynchronous mode of interaction and seldom used synchronous modes of interaction. They expressed their fear of using synchronous mode beyond the technical difficulties of slow servers and lack of proper computer accessories.

Implications

The first implication we could draw from this survey is that faculty members still need training support even though they are pioneers in the adoption of online teaching. They need to understand the full functions of Digital Drop Box and the use of the Virtual Classroom in particular.

To ensure a quality interaction between professor and students and among students themselves, faculty members should try to explore all the possible functions of interactivity provided by Blackboard.

The Blackboard software should be modified so as to serve the needs of better interaction. For example, the faculty should be able to create folders in the Digital Drop Box to place work files of students and comment files from professors. The White Board function should be improved so that when students draw a picture on the white board, the faculty should be able tell who is drawing and be able to monitor the process. It would also be ideal that professor could play video clips or sound clips in the Virtual Classroom.

With better training support and the advancement of technology, e.g. faster servers and more computer accessories, I believe there would be better interaction between professor and students and among students themselves.

Axes to classify Learning Content Units

Annett M. Zobel, Matthias Hupfer, Ulf Schubert, Charles A. Wüthrich
Bauhaus University Weimar, CogVis/MMC
annett.zobel | matthias.hupfer | ulf.schubert|caw@medien.uni-weimar.de

Abstract: In this paper we propose a theoretical framework for structuring pools of learning material cooperatively maintained by students and teaching staff in higher education. In many learning technologies documents are modularised in units we here call *Content Units*. Authors create Content Units and need to sort them into a structured pool. Authors of learning or course documents need to find the Content Units in the pool to integrate them into documents. Our Content Units in documents are exchangeable so that for a specific learner the best version can be picked up from the pool dynamically during the rendering process. For structuring the content pool we use 6 main axes to classify a Content Unit.

Introduction

Teaching Media study courses involves teaching components of the humanities, design, economics and of high-tech disciplines. Given the broad band of material necessary, some institutions have introduced project-based learning to train flexibility and creativity instead of stuffing students with material which will anyway be outdated in short time. Students get project themes, develop and deliver project results each semester. Since project oriented teaching can be most different (e.g. technical oriented or arts oriented) the available tools were not adapted for developing multimedia web based teaching material.

When learning in a project oriented way, teaching staff and students build up information pools cooperatively. When faced with this problem we decided to develop our own famework that meets our special needs of cooperative developing and maintaining pools of information and learning content in the project m^2 [mediasquare]. In the project, computer scientists, interface designers and Media Culture scientists develop an experimental eLearning platform as well as multimedia courseware representing 1000 hours lesson. This courseware will be the basis for a new study course in Media. By the experiences of these developments, production and the planned evaluation studies a university concept for implementing web based learning as well as cooperative production and management of learning material will be developed by the end of the year 2003.

Definition of axes

There are two main requirements for a shared information pool. It should be possible to develop content and integrate it into the pool so easily that it can be managed by students and to render individualized learning and course documents. Individualized means to adapt the content, didactics and (medial) representation to the needs of the learner and his/her boundary conditions. A learner usually has a prior knowledge and a learning objective which specify the learning content to be presented. Learners have different learning styles and prefer different didactical and medial representation. Some learners like to get an overview first and then go into detail and some like to learn with practical examples and other like to start on a higher abstraction level.

To adapt learning documents for instance by exchanging practical samples with abstract samples within an essay it is necessary to modularize documents into here called *Content Units* and to classify these units in a way to be able to pic more user-fitted versions from the pool. Compared to other frameworks [2, 5, 8, 13] it is not just possible to change the layout but also to change the kind of content and didactics dynamicly within the rendering process too.

This *Content Unit* we define (according to "conceptual units" of the Knowledge Management System [12] at the university of Passau) as the smallest textual cohesiv content which can not be splitted in a reasonable way. These Content Units can be integrated flexibly to *Learning Documents*, and by adding course specific content and metadata the course author develops *Course Documents*.

To manage exchangeable Content Units for one unique content we need axes where a Content Unit is defined by choosing one value on each axe. The parameters of the user profile and boundary conditions have to be mapped to a tuple of these axes to find the most fitting Content Unit.

To define these axes we selected suitable elements from metadata standards [1, 3, 7, 9], a didactical ontology from Meder [10] and analysed the structure and classification used by experienced authors. Depending on the subject area, the so called domain, the values on the axes will differ. So authors / experts have to define these values to work cooperatively with a shared content pool.

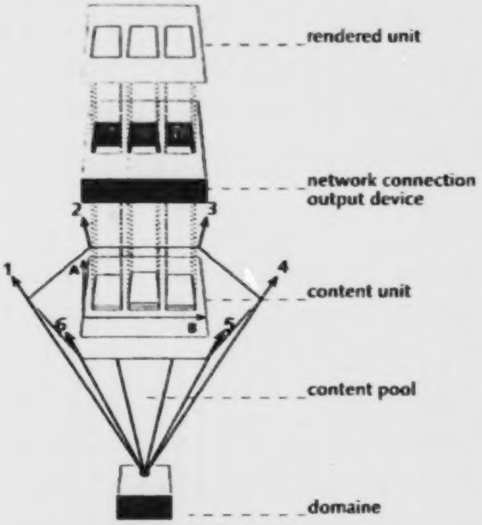

figure 1: axes model of the Content Unit pool

Usually authors differentiate between didactical representation like essay, lecture with slides, sample, exercise type. So the axe *didactical type* (axe 1 in fig. 1) represents the used didactical way to present a content. In the LOM element 5.2 these didactical types are mixed up with media or structural elements like table, diagram and figuret. To represent content more practice oriented or more abstract we use the axe of *abstraction level* (axe 2 in fig. 1). The most obvious axe is the *language* (axe 3 in fig. 1) (English, German, French, ...) also meaning cultural language differences (business English in Egypt). *Content profundity* (axe 4 in fig. 1) describes how deeply a content is presented and can be adapted to the degree of expertise of the user. *Density* (axe 5 in fig. 1) represents with how much text and media a content is explained (referring to LOM 5.4). For instance whether it is an abstract/summary for repetition use or a broad explanation. To get the best learning success the content has to be based on the grade of user experience represented by the *prior knowledge / user level* for instance: freshmen, basic studies, main study period, post graduate (axe 6 in fig. 1). In contrast to the two LOM elements: 5.6 Context and 5.7 typical age we represent these aspects on one axe.

Versions of Content Units

One content can be represented by many Content Units which differ in the values on the described six axes. A Content Unit can be represented by a single XML document with a grammar (DTD) according to the didactical type and a set of metadata.

In these XML documents versions of Structure Elements, Block Elements and Inline Elements can be created. Users have different preferences to use media for learning (e.g. visualizer /verbalizer). To support this the additional axe *Media types* (axe A in fig. 1) provide alternatively use of media like picture, audio, video, text. On the axe *functional complexity* (axe B in fig. 1) the author can define functionalities that can be provided to the user accordingly to his/her cognitive abilities, for instance how many and which links to further information are shown.

These XML documents can be reused in other domains. Because the scales of the axes might be different for domains a new set of metadata has to be created. Which means that the same XML document is another Content Unit in the other domain. To increase the usability of a Content Unit the learner can give feedback if the Unit has not fit to his/her needs in a specific context. The feedback function can create feedback metadata which can be proposed to the author.

Technical conditions

For learning and course documents the *ability of the output device* (for instance screen size or ability to show pictures or VRMLs) and *bandwith of the network connection* define which Media and navigation structures are chosen to render.

Suitable scales for the axes will be experimentally investigated for the Media domains. User and course profiles have to be developed in a way that a mapping of their parameters to these axes is possible within the rendering process. Accordingly to these results the developed rendering process has to be adapted. To represent Content Units and Documents we use XML technology. To realise the rendering process we use an Apache/Cocoon 2-framework [4]. Export functionality will allow to render metadata eLearning standards for the learning and course documents and the courses.

Acknowledgements

The project m^2 [mediasquare] receives funding from the German Ministry of Education and Research within the programme "New Media in Higher Education". Much of this work could not have been done without the help and support from Simona Empoli, Tobias Hofmann [11], Marko Meister and many other participants of the project.

Evaluation of a Homegrown LCMS: All Work and No Play?

Terry Taylor, Nanette Zorn
General Libraries - Instruction
DePaul University
United States
ttaylor@depaul.edu, nzorn@depaul.edu

Abstract: DePaul University Library's answer to the changing demands of the technological revolution was the creation of a homegrown LCMS, the Instruction Builder. When we took instruction online, our ultimate goal was to develop a system that would maximize the efficiency of our teaching and make it easier for students to learn. As we phased in the use of Instruction Builder, it became part of a two-tiered approach to instruction. The online workshop is typically followed by an in-person research session, which teaches more abstract skills such as evaluation of information. The Instruction Builder has solved many of the library's unique instructional issues, but has our two-tiered implementation changed the learning outcomes of the students? This paper reports on a study -- conducted over the course of two consecutive quarters -- that attempted to evaluate the effectiveness of our implementation of the Instruction Builder as an e-learning solution.

Faced with reduced human resources, evolution of learning styles, more students at a distance, and more databases available online, libraries are forced to start taking a critical look at the traditional method of delivering library instruction. DePaul University's solution was to change not only the method of delivery but also the structure and form of the content.

We began to design online instruction in the winter of 1998 using WebCT as the framework for development. There were inherent problems in using WebCT software for this particular purpose. The library is unique in that we have just one classroom opportunity to reach the students. We do not teach quarter-long courses, issue grades, or give tests. We found that, as a tool for library instruction, WebCT lacked the flexibility to adapt to different teaching objectives, and the individualized feedback we wanted to provide to each student about specific research needs was not possible. So in the fall of 2000 we decided to develop a homegrown Learning Content Management System (LCMS), the Instruction Builder.

Developed within the library, the database-driven system provides the following features:

- Content can be broken into discrete sections (modules), and is therefore deployable in parts or as a whole.
- Content can be delivered in more interesting ways by integrating Flash, HTML, and assessment tools in various formats.
- Students are able to complete the exercises on their own time and at their own pace, as well as receive and respond to individualized feedback from a librarian.
- Librarians communicate with each student, increasing and reinforcing learning and fostering a positive discourse about the process and the content.

We designed a modular workshop that teaches the research process using online resources. Each module teaches a single aspect of the research process, and each element of the module teaches a single skill. (An instruction element might consist of one to three screens of information.) The workshop is an integrated component of the information literacy instruction provided in a required freshman composition course (English 104). Each section of the course typically has 23 students, and the course is taught every quarter, often to more than 40 different sections. The students complete the online workshop early in the quarter, and the assignment (built into the workshop) is sent to the librarian designated as the grader for the particular section. The librarian goes into the grading interface of the LCMS and responds to each student's submission by giving individualized research advice and assigning a rating of "complete" or "incomplete."

The results, including both the student's original answers and the librarian's detailed response, are then sent to the student via e-mail with copies sent to the English 104 instructor and the grading librarian. The students then can log back into the system to correct their mistakes and resubmit the workshop assignment for additional evaluation by a librarian.

In phasing the workshop into courses, we decided to continue to have a librarian present a follow-up instruction session in-person and in the library. This session provides an opportunity to review the skills taught in the workshop and to teach the additional, more abstract skill of evaluation of information. As a department, we also felt the in-person session had inherent value for freshman students because it gave the students an opportunity to become acquainted with the physical library and the organization of resources within the library building. In addition, a face-to-face session introduces students to a library staff member in a supportive environment from which they can begin to build a relationship with the library and research. As soon as we began using the Instruction Builder in the winter of 2000, it was immediately apparent to the library instructors that students who had taken the workshop got more out of the in-person session than in years past. In addition to asking better questions and participating more, we found that the in-person session also allowed for peer-to-peer communication and group work, a facet of online learning that our LCMS did not facilitate. Furthermore, since the students submitted the online workshop and received individualized responses from the librarian regarding their research interests, the librarian had already built a relationship with the student before they met face to face. More importantly, each librarian was aware of the parts of the workshop that had been difficult for each student or for the class as a whole. The session could then be customized to the individualized needs of the class.

It is true that this two-tiered approach to teaching library skills did not reduce the time commitment of human resources that were already strained. Instead of just preparing and teaching a session, we now had to grade workshops by issuing individualized responses, which could involve multiple attempts by each user, as well as prepare and teach the session. However, we knew the time was well spent because we could tell from the level of participation in the classes that there were distinct merits to having a combination of online and in-person instruction. We wondered if either one could stand as well on its own since the sum of the components seemed to generate something greater by virtue of the variety of teaching methods catering to diverse learning styles.

In the winter of 2002 we conducted a study in which we selected two English 104 classes with the same instructor. We constructed a pre-test and a post-test to assess student learning of the concepts taught in the online workshop.

- Class A was given a pre-test, took the online workshop, followed that with in-person instruction, and then completed a post-test 2 days after the class session.
- Class B was given the same pre-test, given in-person instruction only, and the same post-test two days after the session.

In analyzing the data, we discovered that the students who had both in-person instruction and online instruction scored an average of 1.25 points better on the 12-question post-test. The students who had only in-person instruction scored, on average, only .1 (one-tenth of a point) better on the post-test. These results indicate that the students who took the online workshop did benefit. Through their marked improvement on the post-tests, these students demonstrated an increased proficiency in the understanding of concepts introduced in the workshop and reinforced through the successful completion of the workshop. The in-person session alone did not have as great an effect in improving the students' scores. There are many external variables that we were not able to control – previous library experience, previous education experience, academic achievement, etc. Further studies need to be done in these areas. Even with those qualifications, we feel that these preliminary results revealed what we suspected all along – the two types of instruction are more effective in combination than either is by itself.

In phase two of the study we attempted to verify the conclusions of the previous study and expand the experiment. The second phase, concluded in May of 2002, included three sections of English 104 with the same course instructor and library instructor as in phase one. In using the same instructor and librarian, we hoped to reduce the impact of different teaching styles as a variable that could affect results. The inclusion of three classes allowed us to isolate and individually assess each discrete component of the instruction. Evaluating pre- and post-test assessments with the third class would help us isolate which part of the library experience was most useful, the online workshop, the in-person session or a combination of both. The instruction for the three sections broke down as follows:

- Class A took the pre-test, took the online library workshop, had in-person library instruction and then took the post-test.
- Class B took the pre-test, did *not* take the online library workshop but did have in-person instruction and then took the post-test.
- Class C took the pre-test, did the online workshop, took the post-test and then had in-person instruction.

We found that the results from the follow-up study did support the previous conclusion. There was a marked improvement in the scores from the post-test for the students that completed the library workshop and had in-person instruction. Students who took the online workshop and had in-person instruction improved their score by 2.3 points. Students who had only classroom instruction improved their score by only .75 of a point. This 1.55 point difference between populations is actually a greater difference than in phase one of the study where the point difference between the two populations was just 1.15.

Even more important, perhaps, is that in examining the results of class C we could tell that the online workshop alone improved the performance of the students on the pre- and post-tests. Students in this population scored only one-tenth of a point lower than the students who had BOTH online instruction and in-person instruction with a librarian. Based on the initial study in the fall, we had concluded that it was the *combination* of in-person and online instruction that was successful in reaching freshman students. What the preliminary results from the first study did NOT show was the value of online instruction alone because we did not have a third class on which to test just the online component while still keeping the variables of instructor and librarian the same.

On the one hand, this result validates the many hours that went into creating the LCMS and the labor-intensive process of continuously developing, animating and refining new online content. What we are doing online *is* working. Students are able to learn the online content and seem to benefit significantly from the way the LCMS facilitates communication with a librarian. On the other hand, it still does not give us definitive information on the effect of the in-person instruction because the pre- and post-tests did not cover the additional content provided in that session. While we recognize that the face-to-face contact has an important effect on students' ability to understand research concepts and provides other benefits mentioned earlier, this result was unexpected. We had assumed that the reinforcement of the workshop concepts in class was a necessary supplement to online instruction. The results indicate that we could probably use the in-class time to cover different material and let the online instruction content stand as a self-contained unit. However, the methodology of this study was not formulated to capture the more qualitative benchmarks of students' research habits. The pre- and post-tests did not in any way quantify how much better a student *feels* personally, knowing a librarian by face and name nor does it show how much time is saved in the long run by becoming acquainted with the physical location and organization of the library.

It is clear that if we were to determine that the qualitative aspects of in-person instruction should be a lower priority considering other demands on our staff time, we could let go of the two-tiered approach and accept an entirely online approach to teaching introductory research skills. We could even do this with some confidence that the students would complete the online workshop with a demonstrable grasp of complex research skills. However, as educators, concerned personally about students and professionally about attrition rates, we find ourselves unable to do that. In addition to the obvious drawbacks for students, this approach could damage a currently strong relationship we have with our faculty. Eliminating in-person instruction for a population that struggles with research could send puzzling and troubling signals to the faculty and cause faculty to question what the library's role is in delivering more advanced levels of instruction. In short, in the eyes of our faculty, it could send a very dangerous message that we don't value classroom instruction and ultimately it could affect how involved faculty become with the library and its staff.

In conclusion, while the design of our LCMS facilitates communication between the librarian and the student, there are still some areas that need to be further developed to facilitate peer-to-peer communication and a more active engagement of all the senses through interactivity, immediate feedback and sound functionality. In other words, if we are going to seriously entertain the prospect of eliminating face-to-face instruction, our system needs to evolve to the level of simulating the effects of one-on-one contact more accurately than it does now. There are very few librarians who would deny the merits of classroom participation and engagement. As we grapple with time constraints and staff reductions we might be forced to accept that it is impossible to supplement online work with an in-person session as we do now, but if we do, we have to be prepared for fall-out from faculty and students. If this is a step we must take, we need to realize that the energy we currently use to grade workshops, develop online materials and teach in the classroom will have to be redirected into taking a much more active role in marketing to faculty and approaching online content development more creatively. Furthermore, we must realize that our homegrown LCMS is an evolving creation, and it must continue to grow and adapt to keep up with the changing needs of students and faculty.

A Web-Accessible Lab Equipment for Training Courses on Chip Design

Peter Rössler
Institute of Computer Technology
Vienna University of Technology
Gusshausstrasse 27-29, 1040 Wien/Austria
roessler@ict.tuwien.ac.at

Abstract: Since terms like e-learning and distant education become more and more popular, today many academic institutions are using state-of-the-art internet technology to provide general information on lectures, lectures notes, on-line courses, educational tools etc. to their students or even handle the whole lecture over the internet. However, this does not work well for practical courses where e.g. students have do some practical examples in a lab using a dedicated test and measurement equipment. This paper presents the project *asix4web* which aims to connect all the input and output user interfaces of a physical lab equipment, used for a training course on chip design at the Vienna University of Technology, to the internet. Hence, students are now able to doing the practical lab exercises for the course from home. As shown with the asix4web project, distant education is also possible for practical oriented lectures and training courses.

Motivation and Related Works

The Institute of Computer Technology (*ICT*) at the Vienna University of Technology is working in the area of chip design since a long time in research, education as well as in projects co-operating with the industry. Several lectures cover a lot of topics starting from the beginners level up to advanced courses. Some considerations were taken into account in order to satisfy the needs of the students and hence to present the lectures in a modern and attractive way by using today's internet technology as transport and communication media in terms of e-learning and distant education.

Nowadays, there exist a lot of internet sites from both academic institutions as well as from companies providing information on chip design, integrated circuits, hardware description languages, tools and some other related topics. For example, (Smith 1997) is a HTML (*HyperText Markup Language*) version of the very popular book *Application Specific Integrated Circuits* from Michael John Sebastian Smith, University of Hawaii at Manoa. However, these web pages are more or less an electronic copy of the paper version without using the special features of the internet, e.g. extensive use of hyperlinks. Another example is the course *Design of VLSI Systems*, an internet tutorial on chip design by Daniel Mlynek from Swiss Federal Institute of Technology, Lausanne Switzerland, and Yusuf Leblebici from Worcester Polytechnic Institute, which makes more use of internet features like hyperlinks or enlargeable images, see (Mlynek, Leblebici 1998). Yet another approach is presented by the U.S. company Aldec. After having registered on their website, see (Aldec 1998), a tutorial on VHDL (*Very High-Speed Integrated Circuits Description Language*), one of the two state-of-the-art hardware description languages used for chip designs, can be downloaded for free and executed on a local PC. A lot of animated figures and images illustrate the content very clear and much more diverting than any ordinary book.

In general, however, for education in the area of natural science or engineering, practical exercises are often a must in order to prove theoretical theses or to e.g. learn the handling of a dedicated test and measurement equipment. Students are not able to do these exercises from home because they do not have the required lab equipment. As it seems at first sight, distant education is not possible for practical courses. Anyway, if it would be possible to give students a kind of remote access to a distant lab equipment, some practical exercises could of course be done from the student's home. That was exactly the goal of the *asix4web* project, started some time ago at the ICT in Vienna: The input and output user interfaces of a physical lab equipment, used for a training course on chip design, should be connected to the internet to allow students to do practical lab exercises from home.

The ASIC Design Course at the Institute of Computer Technology

The *ASIC Design* course from the ICT gives an introduction to the basics of digital integrated circuits design. It consists of a theoretical part and a lab. In the lab, students are implementing a microcontroller which runs a simple application program like a pocket calculator or a chronometer. Due to the tremendous effort and hence costs, the microchip is of course not manufactured in a semiconductor factory but the chip design is implemented in a so called PLD (*Programmable Logic Device*), see (Salcic 1997), which is already physical available and much cheaper. Similar to a PC which has to load an operating system and an application program after power-up, a PLD is initially unconfigured and must be "loaded" with the application prior to the use of it. However, the basic design steps are the same for both designing a chip for manufacturing in a semiconductor fab and designing an integrated circuit which will be "loaded" into a PLD.

All chip design work for the ICTs ASIC design lab is done by using *MAX+plus II* from the company Altera, a suite of EDA (*Electronic Design Automation*) tools which is specially tailored to PLDs from this major provider of programmable semiconductor devices, see (Altera 1997). The last step in the design flow is a test of the chip design in the "real world". For that purpose, a *UP1 Education Board* from Altera is used which is a printed circuit board containing a PLD device as well as some light emitting displays, two push buttons and several switches as general purpose peripheral elements, see right side of (Fig. 1). The PLD on the board is connected via a cable to the printer port of an ordinary PC which runs MAX+plus II. After having programmed the PLD device by using MAX+plus II, the PLD contains the student's chip design. Finally, the design is tested by controlling and observing the peripheral elements contained on the UP1 Education Board. In the case of the pocket calculator example, the buttons and switches on the board are mimicking the calculators keyboard while the light emitting displays work as the calculators display.

The concept of the ASIC design course, described in the last chapter, is well accepted by both the students and the instructors of the course. Some improvements were introduced in order to advance in the context of distant education, see (ICT 2002a):

- Installation of a website containing general information on the ASIC design course and related lectures, time schedules, results of the exams, contact information to course instructors, etc.
- Implementation of an on-line registration system which allows students to select group, time and date for the lab hours over the internet, e.g. from home.
- Providing a free student edition of the MAX+plus II tools for download.
- Providing lecture notes in PDF (*Portable Document Format*) format as well as templates and MAX+plus II design examples for download.

The asix4web Project

Although students are able to prepare their lab example from home by downloading MAX+plus II, lecture notes, templates and design examples, as described in the last chapter, testing on the real hardware (UP1 Education Board) is only possible at the university lab. To overcome this drawback the project *asix4web*, an acronym for *Application Specific Integrated Circuits for the Web*, was started, see (Fig. 1).

A shown in this figure, a UP1 Education Boards is physically connected to a server which is located at the ICT, Vienna. A web server and several dedicated application programs make it possible to upload a chip design from the student's home to the PLD and, further on, to control and observe the status of the input and output peripherals (switches, push buttons and displays) contained on the ICTs UP1 Education Board over the internet, see (ICT 2002b). Hence, by using a standard web browser students have access to the education board for 24 hours a day, 365 days per year and are able to test their lab examples whenever they want to do this. It should be mentioned, that access to the UP1 Education Board is of course not restricted to the students of the University of Technology, Vienna. In general, asix4web provides a PLD-based prototype board to everyone all around the world by using today's internet technology.

More information on asix4web can be found in the asix4web tutorial as well as in the asix4web FAQ section, see (ICT 2002b).

Server at the ICT, Vienna

Figure 1: Basic Concept of the asix4web Project

Conclusion and Future Prospects

The first running version of asix4web was finished in May 2002 and is currently on the web, see (ICT 2002b). It was tested using a number of common used web browsers like Internet Explorer 6.0, Netscape 6.0 and Opera 6.0. Moreover, asix4web was also tested on slower internet connections, like e.g. a 56K modem connection, without any problems or even limited performance. However, asix4web will have to pass it's first "real" challenge in winter 2002/2003, when about 60-70 students will attend the new ASIC design course at the ICT.

As shown in this paper, distant education is also possible for practical oriented lectures and training courses. However, it is obvious that the effort on connecting a complex physical equipment with a large number of user interfaces to the internet can be tremendous. Anyway, it is of course possible for an equipment with a small number of user interfaces, like the UP1 Education Board used for the ASIC design course of the ICT.

Session Abstract: On-line communities of practice use a variety of software tools and applications. These four interactive sessions will explore the commercial, customizable and open source tools currently furthering the development of community. Each tool meets a different community and organisational need. Each of the presenters is the organizer, developer, champion and researcher of the community building and communication strategy they present. This is chance to see available tools put to work and to meet the people who have experience in effectively adapting these resources in the workplace.

The Interactive Sessions for this hour are:

- John Smith & Bronwyn Stuckey - CpSquare Communities of Practice Workshop in WebCT
- Thomas McKegney - Canadian government in Tomoye / Simplify
- Noshir Contractor & Andy Swarbrick Network Analysis in I-know
- Shady Kanfi Bellanet - D- groups for international community building
- Maj. Peter Kilner, CompanyCommand.com and PlatoonLeader.org

These interactive presentations have been teamed into one session to allow attendees to explore a range of technologies available for the support of communities of practice. The products to be showcased ranged from customized implementations of commercial products to purpose built open-source resources for communication across low bandwidth environments. Each of these implementations represents a successful marriage of technology and the values at the heart of community development.

Web Crossing for CpSquare Communities of Practice Workshop: a flexible environment for learning in community

John D. Smith*
Learning Alliance & CpSquare
John.Smith@LearningAlliances.net

Bronwyn Stuckey⊕
Queensland University of Technology
b.stuckey@qut.edu.au

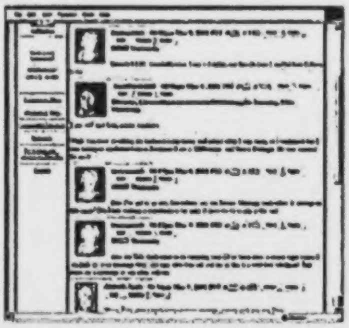
Abstract: Web Crossing, a highly configurable web conferencing platform is described and demonstrated as a useful tool for learning communities. Many of its underlying capabilities are described and several typical extensions are illustrated. Some of the product's advantages and disadvantages are discussed.

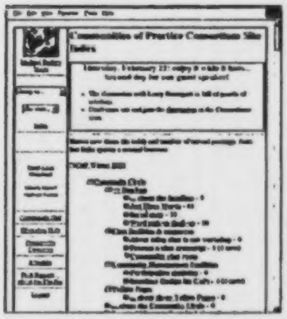
Context

We discuss Web Crossing from our experience, which is largely with smaller, focused learning communities, as opposed to the very large, primarily social "online communities" that were so much discussed during the dot-com bubble. The examples that are offered come mainly from an online workshop that's offered regularly on a Web Crossing platform, from a community of community scholars and practitioners, and from exponents of knowledge management best practices.

Basic features.

At the simplest level, Web Crossing is a web-based conversational engine that runs on UNIX, Macintosh, and Windows platforms. It can organize postings in either threaded or conversational (chronological) modes. A Web Crossing discussion feature that seems to promote sociability is that each posting is accompanied a thumbnail photo of the posting's author. The discussions that contain postings can be gathered together in folders, which can also contain many other discussions or folders. Folders can also contain chat rooms and web link objects. The Web Crossing server supports two programming languages: a rich macro language and Java Script. Together these two languages make Web Crossing highly configurable and extensible.





Applications. Although the basic features of Web Crossing provide a good working environment, we have found that there are several additions to the basic facilities that are important for learning communities. Many of these are available for free at WebXHarbor, a community that uses Web Crossing to discuss and learn about Web Crossing. Probably the most important resource is a Web Crossing instant messenger that provides an indicator when other people are "present" on Web Crossing. Knowing who else is currently logged on is a great aid to the sociability that moves a learning community forward, especially when people make a practice of greeting each other and acknowledging each others' presence.

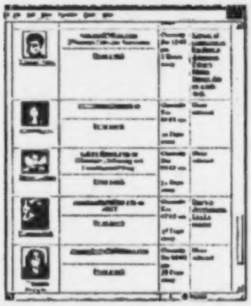
Web Crossing's extensibility serves to make navigation of complex spaces somewhat simpler either through simple devices such as providing a navigation bar or through more complex programs such as the one that produces a dynamic index of an entire directory structure.



We have found that a program that produces a "community directory" is very helpful in suggesting "presence" and involvement because it shows a photo and contact information along with a name and the amount of time since each individual has logged on to Web Crossing.

We have found that collecting data from a learning community (quick surveys that feed information back to the group as a whole or is to be used by community leaders) are an important programmed add-on to Web Crossing. The fact that Web Crossing's Java Script facilities can read and write records from a number of SQL databases is attractive, although we do not have experience in its use.

Readily available examples of Web Crossing discussion spaces include:

- Community Return on Investment conference which was held in June 2001 and brought together many people from the "online community industry": http://roi.webcrossing.com/
- An ongoing online community of programmers, designers, and facilitators who use Web Crossing is at http://webx.webxharbor.com/.

Advantages and disadvantages of Web Crossing.

The following table summarizes several Web Crossing characteristics, each of which can be seen as an advantage or a disadvantage, depending on your point of view or the kind of learning community involved.

	Advantage	**Disadvantage**
Programmability	Complete flexibility as to appearance of additional resources.	Expectations or complexity can increase beyond available programming resources.
Cost: low but not free	A supported product that evolves over time.	Not free.
Security	SYSOP has fine-grained control over user access.	Delegation of security access control to ordinary users demands user expertise.

A Community Information and Knowledge Exchange Tool to Support Organizational Readiness in the Public Sector

Thomas McKegney
Chief Editor
Public Sector Communities of Practice Platform
McKegney.Thomas@tbs-sct.gc.ca
www.compra.ca

Abstract: The Organizational Readiness Office (ORO) in the Chief Information Officer Branch of the Treasury Board of Canada Secretariat decided in February, 2002, to acquire a Web-based tool to encourage and support learning and knowledge sharing initiatives within the IT, IM and Service Delivery Communities.

The Business Case:

The ORO is supporting development of capacity within communities to provide leadership to human resource development issues that align with government's Service Transformation agenda. The argument for acquiring a tool capable of supporting exchanges within communities was that literature on "proven practices" for support of CoPs suggests that one of the most important supports that an organization can provide is an effective mechanism for sharing relevant, validated information and knowledge among members. The ORO recognizes that communities exist because of the interests of individuals, and technology is only relevant if community members feel it furthers those interests. The ORO will be exploring ways that technology designed specifically to support CoP activities affects the development of the IT, IM and Service Delivery Communities, as well as a variety of other public sector CoPs that are being given access to the tool. One government organization also plans an independent formal evaluation of how access to this Web-based knowledge-sharing tool affects several of its communities that have not previously had access to on-line information sharing tools of this type.

By offering access to the tools, the ORO hopes to identify informal communities that exist in workplaces throughout the public service, provide opportunities for participants to be recognized for their expertise, and provide opportunities for community members to develop and demonstrate their leadership skills. As well, the ORO hopes to identify the most effective ways that on-line tools could be best used to achieve the objectives set out in the ORO Business Strategy. These are:

1. Awareness and Engagement
   Given the large number of federal public servants in the IT, IM and Service Delivery communities, and their distribution from coast to coast to coast in Canada, electronic information-sharing mechanisms are the only realistic option.

2. Human Resource Capacity Building
   The ORO is primarily interested in developing capacity of the overall IT, IM and Service Delivery Communities to participate in managing HR issues related to Service Transformation and other organizational changes as the role of government continues to evolve. Because of the nature and magnitude of the cultural change involved, leadership will be required at all levels. Informal workplace communities of practice provide a forum in which leadership skills can be recognized, providing an incentive for further personal development and community involvement

3. Sharing of Management and Work Practices
   Government organizations have many mechanisms for distributing information about formal policies and procedures. However, little if any support has traditionally been provided for informal knowledge sharing among public servants. As individual knowledge and expertise

becomes more important to knowledge organizations such as governments, CoPs are attracting organizational attention. Their informal nature and their focus on work practices encourages sharing of knowledge across departments and other traditional organizational boundaries. This knowledge sharing goes on because of individual interests, regardless of whether the organization recognizes or values it. Providing a Web-based tool can encourage sharing of knowledge on a broader scale to support organizational objectives, but – as noted above – only if it also reflects individual interests.

Selecting a tool

A review of "off the shelf" collaboration tools on the market found only one that met all the key requirements for this project. The basic requirements identified were that the tool must not require any special hardware, software, technical knowledge or sophistication of community members; that any customization needed could be done by community members with no technical support; that no technical support to the communities would be needed; and that community members be able to navigate and post in their choice of French or English. As required by government purchasing policies, a notice of intent to purchase this product was published inviting vendors to propose other suitable products. No other vendor challenged the conclusion that Simplify was the only available product to meet the needs identified.

The ORO requirements were based on its plans to make the tool available to members of the IT, IM and Service Delivery communities. However, there was immediate interest in the tool from a number of "communities of practice," some of which had been in operation for a period of years. However, as informal communities, most had limited organizational support and could not on their own acquire or maintain Web-based tools.

ORO strategically decided that allowing other communities to share the platform would meet its objectives of helping increase awareness of workplace communities, and encourage a co-ordinated approach across government to support for CoPs. This made the tools accessible to communities that could otherwise not have afforded any tools of the sophistication of Simplify. It also encouraged sharing of experiences and ideas among various communities, helping to avoid costly and unnecessary duplication of software evaluations, license fees, server maintenance, training, etc. The vendor has taken a very enlightened approach to this sharing of the tools, and has shown no hesitation to help the ORO develop innovative ways to test the limits of the product design

ORO involvement in the platform has given increased legitimacy to CoPs, and has provided an opportunity to bring leaders of many CoPs together on a monthly basis to discuss issues related to CoP activities in a federal government setting. Often the interest in the ORO platform comes from individuals who are looking for "the tool" that will create or support a community for their organization. It is useful for these individuals to meet with other community leaders who know from experience that technology does not create community.

This platform is also giving the ORO an opportunity to evaluate modern management theories that suggest individuals who are passionate about their work will share their enthusiasm and knowledge with others if they see this as a value to themselves and/or their community. ORO's decision to provide this tool for community use is seen as evidence that government recognizes that CoPs can play a role in change management, if they are given the opportunity and tools needed to participate effectively. It also reflects a degree of respect and trust for communities, recognizing that they are informal structures that are neither directly accountable to nor formally part of decision-making structures. However, the risk of misuse is considered low given that community members are public servants who occupy positions of public trust.

The Product

Simplify is provided by Tomoye Inc of Gatineau, Quebec. The original product was developed for the Food and Agriculture Organization in Geneva to support knowledge exchange among researchers and experts within the global fishing industry. While the technology is based on email and a Web repository just as many other discussion-support solutions, Simplify is specifically designed to support development and activities of communities of practice.

The ORO made a conscious decision to have the Government Informatics and Telecommunications Service (GTIS) configure and maintain the server needed to support this platform. This decision was taken to encourage GTIS initiatives to develop capacity to support innovative, cross-jurisdiction services. GTIS offered service at a cost comparable with a private sector supplier, and is able to allow access by public servants both via the Internet and the government Intranet.

Dgroups Overview

Shady Kanfi, Bellanet
Canada
skanfi@bellanet.org

Abstract: Dgroups is a partnership whose aim is to nurture and support many kinds of groups and communities related to international development. Whether supporting a team, a group, a network, a partnership or a community, the partnership hopes to provide an environment that is simple, non-commercial, respectful of privacy, and targeted at low bandwidth users in the South. Dgroups is also the name of the platform that exists at www.dgroups.org and of the software application that was developed.

Who is Dgroups ?

Current partners include Bellanet, IICD, OneWorld, UNAIDS and DFID. The platform was developed and hosted by Bellanet and is supported by all partners with more joining all the time. Current participation is limited to Dgroups partners and their respective networks of projects and stakeholders.

Why Dgroups?

As part of the overall rise in Internet use among international development organisations, recent years have seen an ever-increasing number of organisations that want or need to host online groups, events, dialogues or communities. Instead of continuing to develop separate or one-off solutions, with unconnected spaces and non-transferable skills and information, the Dgroups partners decided to come together and support a common and re-usable platform not just for each other, but ultimately for the entire development community.

The partners see support for Dgroups as a way to develop such a public platform, to provide valuable services to their respective stakeholders and networks, and to create an easy way for people to find out about groups and communities of interest to them from the central Dgroups site.

Why create something new? Because until today, the partners know of no comparable service which is as simple, non-commercial (no end user cost/advertising), respectful of the privacy of personal and group information, and targeted at low bandwidth users in the South.

Fostering strong communities is an art that involves a subtle understanding of group dynamics, the use of good facilitation techniques, and the use of appropriate tools. The successful combination of these factors will help foster an environment where individuals identify with, and easily interact with, their group. The Dgroups platform focuses on the development of appropriate tools, while Dgroups partners together try to develop the facilitation and community management skills that are necessary.

Background

A major focus for Dgroups is to service users from developing countries with low bandwidth connections to the Internet. Making sure that participants from the South can be "first-class citizens" in our online spaces has resulted in the adoption of email-based discussion at the core of all group spaces. Email offers the flattest learning curve, the lowest bandwidth requirements, and benefits in terms of push vs. pull technology for both Southern and Northern participants. Mailing lists, the ultimate expression of email based "groupware," have thus become the core Dgroups technology.

But email-only interaction is not sufficient for many. With good intentions, many push the technological envelope by innovating with web-based repositories and databases allowing the sharing of various resources (news, events, project information, documents, links, contact information,

organizational information, etc.). Yet Dgroups partners have realized that not rooting a knowledge or information sharing effort in the context of a specific and well understood group of people severely undermines that effort's chances at success and sustainability.
Groupware is not a new concept, and "Communityware" is a popular evolution of this idea. Unfortunately few, if any, retain a low-bandwidth orientation (i.e. a focus on email-only participation) without compromising on web-based functionality and without commercial disadvantages (i.e. high costs, advertising, unacceptable privacy policies, or unacceptable use of personal or group information).

Thus evolved the Dgroups "workspace." Half mailing list, half 'group home page,' a workspace is a hybrid tool that starts with the ease of participation that a mailing list provides and allows a group to expand into the arena of web-based information sharing in a simple fashion and at its own pace.

Design Vision of the Dgroups Workspace

There are three core elements to the standard Dgroups workspace. In order of priority they are: the discussion, the people, and the related resources.

First and foremost every workspace is oriented around a single mailing list based discussion. The website acts as a public or private 'home base' for this discussion by providing access to browse discussion archives, and is usually augmented by highlighting recent postings on the home page, or by offering a full text search capability. The discussion is considered the fundamental glue that holds each community together regardless of whether or not it serves objectives from a larger context (such as organisational mandates, or upcoming events).

Second, workspaces highlight user profiles and individual participation in the group. A strong sense of who people are in a community allows one to establish the crucial context in which messages are sent, information is shared, and knowledge is learned. A better understanding of a user's pattern of activity, their individual background, or their organisational affiliation helps other members of the group judge the value of the information they glean.

Finally, workspaces offer groups the capacity to collect, manage and disseminate related resources and material. Often this functionality is used by and for the groups themselves, but sometimes it is used to disseminate information publicly when a Dgroups workspace is open to the public. Resource types include links, Word files, PowerPoint presentations, spreadsheets, news items, bibliographic references, audio files, video files, etc. The system automatically converts some of these resources to web pages for ease of viewing. Even though management and editing of these resources may be the principle objective of a given group (such as a team developing a joint project proposal) the emphasis in the workspace is not on the resources themselves, but on the discussion and the people involved in the management or editing process.

Other features such as calendars, voting tools, multiple mailing lists, databases, photo albums, etc. are all possible and some are currently being used, but they are not central to the design and use of the platform. An important goal of Dgroups is to remain focused on nurturing a single group identity through dialogue and through a better understanding of one's fellow group members.

US Army: CompanyCommand.com and PlatoonLeader.org.

Maj. Peter Kilner,
CompanyCommand.com and PlatoonLeader.org
Peter.Kilner@usma.edu

Abstract: CompanyCommand.com and PlatoonLeader.org connect platoon leaders and company commanders in the Army allowing them to share what they are learning real-time, laterally across the entire organization. In addition to better preparation and learning while in the job, participating in these communities ensures that key experience is not lost. These communities also facilitate a culture change that encourages collaboration and the sharing of knowledge and experiences. Considering that all Army officers-literally thousands each year-command a platoon or company, the impact of this concept is phenomenal.

Pete Kilner provides both a scholarly and practitioner oriented approach to organizational learning and knowledge management with a focus on the development and organizational impact of distributed communities of practice. Pete is a founding member of two robust distributed communities of practice in the Army: CompanyCommand.com and PlatoonLeader.org. He is part of a leadership team that facilitates the efforts of over 20 volunteers who act as project managers, online discussion facilitators, and subject matter experts with the primary focus of creating and delivering value to these communities of practice.

The team is beginning to see the fruit of their work. Leaders throughout the Army are accessing knowledge, sharing ideas, and tapping into the experiences of others. The Web sites log over 55,000 unique visitors, making over 1.5 million hits a month who download the data equivalent of over three Microsoft Encarta Encyclopedias.

These sites capture not only the Intellectual Capital but also the spirit of the organization.
The websites are running off of php and perl scripts. PlatoonLeader.org represents our push toward a more automated community that requires very little technical expertise to run/operate. PlatoonLeader.org is running a variant of the widely popular PHP-Nuke Portal script. The branch that we are using is MyPHPNuke. This is a complete "portal" solution that is available for free (http://www.myphpnuke.com). While the creators call this a portal it is easily turned into a community of practice. Once installed on a server this free software has an Article Section, Threaded Discussions, Live Chat, Links Database and much more. Some setup and tweaking is required but the software comes with a robust administrative area that is controlled through a simple web page interface. Many of the commercially available "portal" and/or community solutions offer the same sort of function but at a much greater cost. No matter what solution is chosen it must always be tailored to fit the needs of the enterprise. Starting with a free, open source product allows for greater customization and innovation for the company that is using it.

Recently the team was recognized by Fast Company's Fast50 (March 2002 issue) for the model they have created. Additionally, the companycommand.com and platoonleader.org communities of practice were recognized by the Army as the Army's Most Innovative Knowledge Management Initiative this year. As a result of the impact these communities are having on the way the Army learns and shares knowledge, Army senior leaders have asked the team to work full time in the development of a Center that provides strategic planning and development of online communities of practice throughout the Army.

Network Analysis with I-know

Noshir Contractor
University of Illinois
contractor@uiuc.edu

Andy Swarbrick
University of Illinois
swarbrick@uiuc.edu

Abstract: Because information transacted over electronic media such as the Web can be stored in digital form, a new generation of software called "collaborative filters" or "communityware" (Contractor, O'Keefe, & Jones, 1997; Kautz, Selman, & Shah, 1997) can be used to make visible the work communities' virtual social structure. One such tool, IKNOW (Inquiring Knowledge Networks On the Web; `http://iknow.spcomm.uiuc.edu/`), has been designed by a team of UIUC researchers to assist individuals to search the organization's databases to automatically answer questions about the organization's knowledge network, that is, "Who knows what?" as well as questions about the organization's cognitive knowledge networks, that is, "Who knows who knows what?" within the organization.

Unlike traditional web search engines that help an individual search for content on the web, tools such as IKNOW search for content and contacts (direct and indirect). In addition to being instantly beneficial to users, they also provide researcher and e-moderators with an opportunity to unobtrusively and reliably study the influence of Communityware on the co-evolution of knowledge networks.

Noshir Contractor (http://www.uiuc.edu/ph/www/nosh) is a Professor of speech communication and psychology at the University of Illinois at Urbana-Champaign where he teaches courses and doctoral seminars on organizational communication processes, communication network analysis, dynamic systems analysis, collaboration technologies, and quantitative research methods. His research interests include applications of systems theory to communication, the role of emergent communication and knowledge networks in organizations, and collaboration technologies in the work place. His current research focuses on collaboration, including the role of computer- based tools to augment collaboration and group decision-making processes in team and organizational settings.

Online Media Juke-Box

Luca Botturi
Istituto Comunicazione e Formazione
Università della Svizzera italiana
via Giuseppe Buffi 13
CH-6900 Lugano
luca.botturi@lu.unisi.ch

Abstract

This interactive session presents *Online Media Jukebox*, a web interface for delivering online one or more selections of digital resources (texts in any web-compatible format, streaming video and audio, links) with a minimum of technical competencies. The software is a easy-to-use tool which has proved useful and of simple usage in its application for a course at the Università della Svizzera italiana.

Intended audience

The interactive session is intended for teachers of all levels and education practitioners who would like to try out a simple tool for collecting online resources. No particular prerequisite is necessary.

Software description

The presented software is a simple runtime database in JavaScript designed to contain online resources of different formats and intended to gather e.g. a case study. Supported media types are:

- texts (any Web-cpmatible format)
- Streaming video and audio (on the same or on a different server)
- URLs

Documents are catalogued according to the media type, but can as well be ordered with other criteria.

The construction of a collection of resources is done simply by editing a text file with the description of the digital resources. It has been used for implementing online case studies on more than 20 institutions in the course *The Institution in the Context of Society* at the Faculty of Communication Sciences at the Università della Svizzera italiana in Lugano, and is available for reuse.

Further developments are foreseen in year 2003 with the development of an online repository of digital resources and an application for selecting them and producing automatically an *Online Media Juke-Box*.

Software presentation

The software will be presented according to the following perspectives:

1. Student interface
2. Web and software architecture
3. Implementation: how to use it
4. Demo: Case study on Institutions - a possible scenario
5. Discussion

Collecting digital documents will also be the chance for discussing related issues such as

- Copyright management issues
- Reuse and re-contextualization of learning resources
- Quality of Internet information

Proposed length

1 hour.

Presenter's qualifications

After his graduation at the University of Lugano with a thesis on educational adaptive hypermedia systems and educational design (ALSTOM Power 2000 prize for the best graduation), Luca Botturi is currently Ph.D. student at the same university with the topic *Designing Technology-dependent Educational Environments for Higher Education*.
He is fellow student of the doctoral school *NewMinE – New Media in Education*, funded by the Swiss National Science Foundation (www.newmine.org).
For the Istituto Comunicazione e Formazione he is involved in several e-learning projects as media designer, among which SWISSLING (www.swissling.ch). In the same institute he is coordinator of the seminar *Cognitive models and technologies*.
He was local co-chair of the ICNEE 02 International Conference on New Educational Environments (Lugano, May 8th-11th 2002).

Professional Development + Instruction + Minerals = A DVD that Rocks!

Abstract: This paper details the creation of a multi-purpose DVD. First, the DVD can be used for professional development to teach P-12 teachers how to integrate a DVD into an instructional setting; a lesson plan is included that helps to illustrate the use of a DVD in the teaching of a topic. Second, the DVD, which contains instruction about rocks and minerals, can be given to students to use on either a computer with a DVD drive or on a DVD player connected to a television. Third, the DVD serves as a promotional tool; in this case, the DVD helps to promote both the mineral museum that is on the campus of Youngstown State University and Youngstown State University itself.

Introduction

This paper focuses on the creation of a DVD-based multimedia program that spotlights the subject of geology. DVD authoring allows for inclusion and integration of a variety of digital resources such as digital video, still images, audio and Web links. Ability to include subtitles and interactive menus adds to the instructional appeal of DVD. This DVD is a multi-purpose tool that can be used for professional development, instruction, and as a promotional tool.

Design and Development of the DVD

The authors are fortunate to have an excellent mineral museum located on their campus. Access to the museum facilitated the collection and/or creation of digital images, virtual reality movies, and digital lectures, along with handouts, for inclusion onto the DVD. Instructional components were collected and incorporated into an instructional DVD, which also contains a model lesson plan plus instructional techniques that can be used by teachers in their classrooms to integrate the DVD into an instructional setting. Design and development of the DVD was accomplished using a Power Mac® G4 computer and Apple DVD Studio Pro™ software.

Instructional

As with all multimedia projects, the authors had to address various instructional design issues. Four instructional design areas required the most attention. The first area was deciding what information to include for a multimedia presentation. A second issue was deciding the delivery method for the multimedia presentation; after examining the advantages and disadvantages of various delivery modes, a decision was made to create a DVD. Use of the DVD created another instructional design issue: what to do in a situation where the learner is accessing the information, especially handouts, via a DVD player connected to a television. The final instructional design issue was the layout of contents and navigational design of the DVD to make the DVD user-friendly for diverse range (age, knowledge of subject matter, and technological abilities) of end-users.

To include various types of content (video and other files) and to take full advantage of the storage capacity (4.7 GB) of the DVD disc, the authors choose to create a hybrid DVD, which contains files that comply with the DVD video and audio standards and files that do not (Apple Computer 2001). In this particular project much of the video complies with the DVD standard and, therefore, can be viewed and navigated using most DVD players. Some of the content such as QuickTime VR (virtual reality) movies, and supplemental instructional materials require a computer system with a DVD-ROM drive to access and utilize them. By using a hybrid format, a single DVD disc can contain the high quality video, characteristic of DVD, and the supporting instructional materials and files necessary for multiple uses.

Professional Development

Effective, efficient, and appropriate use of technology in today's classrooms is critical. However, technology cannot be the major focus, but rather it needs to be integrated seamlessly with instruction so that the subject content is the emphasis, and not the technology. To accomplish a seamless integration for instructional use in the classroom, professional development that concentrates on technology integration must be given to teachers. Modeling the instructional strategies for teachers about how and why to integrate media and technology in their classrooms can be beneficial in transforming a traditional teaching approach to one that is more progressive. The instruction brought about in the classroom can change the way students learn about the content and certainly makes it more motivating and personally more interesting. When making instructional decisions about web-based and/or multimedia learning activities, teachers need support and motivation for the development of the project. An instructional lesson plan was designed that included learning outcomes, concepts to learn, purpose of lesson, strategies, and assessment. This plan may be adapted for different concepts and grade levels.

Additionally, information is contained in the professional development section that describes how the teacher can utilize the DVD for different instructional settings. This component covers ways that the DVD can be incorporated into a whole class lesson; in addition, there are suggestions as to how a teacher can use the DVD as a learning tool on an independent basis at school or at home.

Instruction

The DVD is also designed to be used by students of various ages. Because of that, the geological information included on the DVD was selected to be visually appealing and to allow the students to have an interactive learning experience. Much of the video in this project provides access to subtitles, a feature that should prove useful to hearing impaired users. To maintain a student's interest, the DVD contains information in different forms. Some information is present in text form. Other information is presented by using images with accompanying audio. There are also virtual reality movies of some of the minerals housed in the museum. To add a touch of humor and a "fun" feeling to the learning experience, video of Dr. Beiersdorfer, co-author of this article and professor in the Department of Geology and Environmental Sciences, singing about rocks was incorporated into the DVD.

Promotion

Besides using the DVD for professional development and instructional purposes, the DVD can be used as a promotional tool. The DVD can be given to individuals (adults and/or children) so that they can see images of the minerals housed in the museum and learn, on an independent basis, about those minerals. In this section, the viewer is encouraged to visit the onsite and online mineral museum to see the minerals on display. Promotion of the museum is done via a video tour of the museum. A link to the museum's website is part of this aspect of the DVD.

The mineral museum is not the only promoted location. Youngstown State University is also a featured component. This part of the DVD permits the student to enjoy a virtual tour of the University. Additionally, for individuals who access the DVD via a computer that is connected to a printer, undergraduate and/or graduate applications can be viewed and printed.

Conclusion

DVDs are no longer just for movies! Access to DVD burners permits the creation of instructional materials that can be used in a variety of ways. With careful thought and good design, use of a hybrid DVD format allows inclusion of video, audio, and other media and data files onto a single DVD disc. The increased storage space provided by DVD allows for the inclusion of various types of content making the creation of a disc that has content suitable for multiple purposes a possibility.

The DVD is an innovative teaching tool that certainly will capture the interest for students in a discipline area, such as geology. Opportunities and access for students to view and analyze minerals in a science class can prove to be expensive, and often the school district lacks the laboratory materials to provide an enriched learning experience for its students. Using the capabilities of a DVD can overcome such obstacles.

Developing Online Courses using Robohelp

Introduction

With the dramatic development of the Internet, universities and colleges are zealously developing online courses and programs. A lot more care needs to be taken in the development of an online course than a traditional course, specifically in overall design, look and feel, navigational convenience, and interactive content. Robohelp from Ehelp Corporation provides a powerful (and familiar to Windows users) environment for developing and publishing course content within course management software or on the World Wide Web. This Interactive Session will demonstrate how to create comprehensive content for Online courses and Programs.

Software to be Demonstrated

Robohelp, from Ehelp Corporation Navigation is the perfect tool for developing online content with point-and-click ease. When used with course management software such as Blackboard or WebCt, it is possible to create professionally developed courses rapidly and with lower cost. Anyone familiar with Microsoft Office Help has used the Robohelp paradigm in which topics are created in books and can be individually read and sequentially navigated, searched by keywords, or navigated by index topics. If you are viewing this document in Microsoft Word, click on *Help -> Contents and Index* to see how content created with RoboHelp is presented.

Significantly, output of Robohelp is a folder that can either be loaded as content into course management software or published directly as a website on a web server. On the development side, users can use RoboHelp's built in HTML editor, or substitute one they are familiar with. The environment supports editing at either the tag level or WYSIWIG (what you see is what you get).

Interactive Session

The presenters will show how to create content for a multi-book educational topic. This will demonstrate how to create a new project, new books, new topics and how to edit and ultimately generate the website.

If there is a connection to the Internet (wireless or wired), the presenters can demonstrate both how to publish the project on a website and incorporate it directly into Blackboard.

Audience

This interactive session is for educators who are interested in learning effective ways to develop powerful professional courseware easily and quickly for online courses and programs. There are no prerequisites, but participants with a course in mind to develop content for will benefit most from the presentation.

Proposal for AACE E-Learn 2002

The Integrated Electronic Course Portfolio (IECP)

Yitna Firdyiwek
ybf2u@virginia.edu

As is well known by now, the World Wide Web has afforded teachers broad access to information and and the possibility of well integrated work environments for collaborative activities. However, while surfing, chatting online, and building personal web pages are fairly easy activities, developing even moderate scale interactive content sites that organize and maintain student work remains too difficult for many. There are numerous programming and infrastructure issues that need to be resolved, and carefully selected appropriate tools that need to be in place before the power of Web-based connectivity can be tapped directly and constructively by teachers and students with average technological skills. Thus, the viability of web technology for supporting teachers on a wide scale has been late being realized.

Part of the problem stems from the limitations of the Web itself. Though it's a powerful tool for delivering information, when it comes to organizing what it delivers, the Web by itself is rough and chaotic. Because of this weakness, the Web cannot be taken advantage of fully without additional tools such as databases for structuring the information it delivers. Integrating the web with databases allows for the functions of "delivery" and "organization" of documents to be accomplished via tools that are appropriate for each function. With the advent of systems that make building web-based interfaces for databases easier, the possibility of collecting, storing, and disseminating large amounts of documents in a manner that simulates paper-based classroom interactions is within the grasp of teachers.

Another part of the problem that hampers teachers in the use of the Web for collaborative classroom activities is the design of such tools. Even when web-database integration is leveraged, the design of the user interface for such tools can pose severe limitations stemming from the fact that most of the tools are either not designed with teaching and classroom environments in mind, or designed at great cost and for specific teaching environments only. Another related problem involves the dynamic nature of any rich teaching environment. To allow teachers and students to be creative in their use of the tool without diminishing the dynamism of their exchanges a tools needs to be extremely flexibile, easily customizable, and either transparent to, or part of, the content and pedagogy at hand.

The interactive session being proposed for this AACE conference involves the demonstration of the Integrated Electronic Course Portfolio (IECP also known as E-folio). Developed for use in the management of portfolio-based writing instruction, the tool was initially designed to respond to two specific problems posed by that method of teaching: handling a large number of documents produced by students, and fostering interaction and collaboration by teachers and students over the work they produce. Using Electronic Performance Support as a method of software design, the tool was developed in collaboration with writing instructors who had used portfolio-based writing instruction and who had identified the two most severe problems that kept them from successfully implementing the portfolio method. While still a tool designed primarily for handling writing-intensive courses, the IECP has been effectively used in a variety of teaching environments from high-school to graduate level courses. Through an interactive demonstration of the IECP participants will be able to see how the tool has addressed the problems of harnessing web-interactivity and producing an effective user interface design.

Developing and Authoring Multimedia Presentations Using Trivantis "Lectora"

Dr. Ted Folwer
College of Education
University of Cincinnati
United States
ted.fowler@uc.edu

Abstract: Trivantis *Lectora* is a software package allowing easy creation of interactive multimedia courses, tutorials, portfolios, and presentations for Internet websites or self-contained CD-ROMs. Four applications are demonstrated: professional teacher portfolio, tutorial presentation on electrical safety, interactive instructional protocol for classroom management, multimedia kit for use by students. All contain text, images, audio, and video demonstrating the power of the software. The code that was written to create the applications is shown and explained along with the variety of tools included with *Lectora*. The authoring of a simple multimedia presentation is interactively demonstrated using the "book" metaphor basis of *Lectora*. Emphasis is placed on identifying the instructional principles upon which the applications and illustrations have been built, including Borich's five key teaching behaviors, constructivist learning, and social interaction during the teaching/learning process.

Introduction

Trivantis *Lectora* is a software package that allows easy creation of interactive multimedia courses, tutorials, portfolios, and presentations that can be published as Internet websites or as self-contained CD-ROM applications. Four of these applications were demonstrated during the interactive presentation:

- professional teacher portfolio
- tutorial presentation on electrical safety
- interactive instructional protocol for classroom management
- multimedia kit for use by students

These applications contain text, photographic images, audio, and video. *Lectora* also supports Shockwave, Flash, HTML, Java, and JavaScript.

Objectives

- Participants observed several practical applications of the *Lectora* multimedia software package.
- Participants came to understand the manner in which the applications were developed and programmed.
- Participants came to understand the fundamental capabilities and operation of *Lectora*.
- Participants understood the educational and instructional principles that were used as a basis for construction of the various applications demonstrated.

The presentation was appropriate for anyone with a general understanding of multimedia applications and was intended for all grade levels preK-12, higher education, and industrial/agency training.

Interactive Presentation

Each of these applications was be presented in a way that demonstrated the power of the software. The simple code that was written to create the applications was shown and explained. The variety of tools included with *Lectora* was exhibited within the context of the applications in which they were used. Finally the authoring of a simple multimedia presentation was demonstrated using the "book" metaphor that is the basis of *Lectora*.

The professional teacher portfolio was produced by a graduating English major and makes use of many of the features of *Lectora*, including video, exhibits of student and teacher work, Flash animation, and complex indexing. The electrical safety materials were developed by the presented in conjunction with the Centers for Disease control, National Institute for Occupational Safety and Health (CDC, NIOSH). A variety of techniques have been used to optimize the knowledge and attitudinal impact of the course materials, including photography, linked text, video, branching, and multiple entry points. The teacher protocol material makes use of branching contextual video to demonstrate a variety of teacher instructional skills with reflective statements by the teacher in order to drive home the critical instructional acts. The multimedia kit demonstrates a technique that provides appropriate scaffolding for project-based learning. A variety of resources are provided students to build a multimedia presentation based on audio recordings of Thane Maynard, *The Ninety Second Naturalist*, from the Cincinnati Zoo. Students, using *Lectora* or other multimedia packages, are able to work in small groups to assemble accurate and entertaining information for class presentation using a "jigsaw" cooperative learning approach. Appropriate scaffolding is supplied in the kit to allow students to focus their learning during a class project, aiming to develop valuable intellectual and group process skills.

Emphasis was placed on identifying the instructional principles upon which the applications and illustrations have been built, including Borich's five key teaching behaviors, constructivist learning, and social interaction during the teaching/learning process. *Lectora* supports these principles well and is also able to be integrated with *Blackboard* to further support defensible instruction and training.

Participants were able to work through some initial development examples using interactive small-group worksheets designed for the session: here is the task, think about it, order the steps, tell me what to do. This allowed for maximal participation of a wide range of experience levels and assured interaction among the participants. The later part of the session was be driven by participant questions and reactions.

The Challenge of Turning Professional Development into Professional Practice

by
Sharon Friesen and Pat Clifford
Galileo Educational Network

Introducing new technologies should never be about pouring old wine into new bottles. Students must be given the opportunity to think in compelling ways each time they pick up a digital tool. In a general sense, technology should allow students to do things at a level of complexity and sophistication impossible without a computer. It should allow them to create, not simply consume and reproduce knowledge. And technology use in school should have more in common with students' out-of-school experiences with digital environments than with digital textbooks and worksheets.

Teaching to accomplish these goals requires a commitment to inquiry-based learning, and teachers who think differently about curriculum, teaching and learning. The Galileo Educational Network is a professional development and research initiative focused on the kinds of fundamental changes to teaching, learning and staff development that information and communications technology both requires and enables. Providing professional development both onsite and online through an innovative professional development service called IO (Intelligence On-Line), we are assisting teachers make necessary changes to their professional practice.

The Galileo Educational Network was formed in 1999 to provide this kind of professional development in a face-to-face environment in order to assist teachers to integrate information and communication technologies (ICT) into teaching and learning in core academic areas. In September 2002, we will complement the proven success of our on-site approaches to professional development with an on-line environment that supports teachers as they learn to plan and think in new ways. Drawing on three years of intensive on-site work, this new initiative carries our commitment to school reform into an e-learning environment.

It is clear that in order to infuse information and communication technology into the world of the classroom in genuinely effective and innovative ways, fundamental changes to our understanding of teaching and learning are required. We need to produce and develop teachers who can move with confidence and skill away from old teacher-centered structures and ideas about their work. Such teachers must learn how to create compelling project-based inquiries for teaching and learning if educational investments in technology are to bear fruit. This shift requires a fundamental cultural change:

- Curriculum must become increasingly learner focused, and learner driven

- Learners must become far more deeply engaged in meaningful tasks that are of value to self and to others.
- Learners' experience with technology in school must become much more like the experiences they currently have outside school

The on-site work of the Galileo Educational network has begun to provide compelling answers to the following questions:

- What are the impacts on student learning when teachers learn new things in new ways?
- What is the nature of inquiry-based learning for teachers and students?

Our on-line initiative addresses a further question:

- How can on-line professional development for technology integration result in changed professional practice?

Intelligence On-Line (IO)

Technology is leading the way with conversations that need to be held at every level of formal education. How do we create personalized learning environments rather than the generic, teacher-centered ones that continue to characterize so much of children's experience at school?

Effective, highly personalized on-line environments must begin to discard the assumptions of distance learning, where courses, lectures and materials are still delivered, essentially in one direction, from instructors to learners. They must even go beyond the interactive supports for such courses now provided by bulletin boards and chat environments. Personalized environments push these edges to require learners (in our case, teachers-learners) to create something new. It is a move away from a central metaphor of course delivery. The root metaphor, itself, changes. Knowledge is not delivered; it **grows** in unpredictable ways because learners move through an e-learning space according to their own needs, intentionally connected to others. Participation in this space makes it grow for you, over time and through your use and interaction. For each learner, the space becomes what it is **because** each learner uses it in the ways that make most sense to them.

In February 2001, the Galileo Educational Network Association formed a partnership with Axia Netmedia. Together, we created an online Intelligence Online (IO). Our goal is to help teachers develop and refine environments where their students learn **with** technology as opposed to learn **about** technology.

Galileo and Axia share a strong fundamental belief that successful teacher professional development:

- Is ultimately about students and improving student learning
- Must be viewed as an ongoing and integral part of teachers' professional lives
- Must be focused on specific outcomes that are desirable to both teachers and stakeholders

Through IO, teachers can learn to create highly engaging inquiry-based projects "in which the desired learning outcomes…[are] the construction of new knowledge and understandings rather than merely summarizing what…[is] already known about a topic" (Jacobsen, 2001b p.20). There is classic content available in this place, but it goes much further than that. They will have access to tutorials just in time, not just in case they might need the information six months down the line. Teachers will be able to collaborate with others, consult with world-class experts, and see powerful examples of what learning with technology truly ought to mean: what can students do with technology that they have never been able to do before, or what can they do more deeply, more powerfully, with more passionate engagement than paper and pencil have ever allowed. And, most significantly, teachers will learn about effective technology integration by being immersed in a culture of use in which they will "experience first hand the learning opportunities they…[will then be able] to provide for children" (Jacobsen, 2001, p.19).

Currently, much of what is available to teachers on line takes a landfill approach: provide hundreds and hundreds and hundreds of examples of teacher-generated units and hope that some of it is useful. More recently, enthusiasm for on-line repositories objects has added to the heft of available learning objects without addressing fundamental issues of how teachers might use such objects in robust inquiries. In such environments, "good" generally means "lots". IO is far more sharply focused than this. It is an innovative move to on-line environment that becomes more particular to teacher needs, questions and interests the more they use it.

Conclusion

It is our belief that effective e-learning environments for professional development must learn important lessons from what works in face-to-face environments while utilizing the particular character of communications and information technology in new and exciting ways if we are to make wide-spread progress in changing the face of teaching and learning in schools. This presentation

- demonstrates both the ways in which new approaches to professional development in face-to-face environments address gaps in current practice identified in the research literature;
- suggests ways in which what we have learned can be translated into e-learning environments
- suggests directions for the fruitful marriage of face-to-face and e-learning professional development for maximum effectiveness.

Building Different Bridges: Technology Integration, Engaged Student Learning, and New Approaches to Professional Development. *Paper presented at AERA 2001: What We Know and How We Know It, the 82nd Annual Meeting of the American Educational Research Association*, Seattle, WA: April 10 - 14, 2001.

In-service Development for Educational Assistants

Abstract

The Special Needs Opportunity Windows (SNOW) Project is an online provider of professional development opportunities and resources for educators and supporters of students with special needs. Using Web-based courseware tools, SNOW offers training and curriculum materials along with interactive discussion forums to assist Ontario educators in applying experience and strategies to benefit all learners. The Inservice Development for Educational Assistants (IDEA) workshop series provides educational assistants with the opportunity to receive Web-based training to support learners who have special needs.

With budget pressures and crowded classrooms, demands on educators today have never been greater. Classroom management becomes more complex as Ministry guidelines to handle students with special needs become more comprehensive. Educational Assistants provide support to teachers by working individually with students to assist with their responsibilities. For such a paramount role within the Ontario education system, an EA is inclined to tread through uncertain waters in an effort to help, though more often than not they are unqualified to do so. In some cases, an EA has little to no experience in dealing with students who have special needs.

One solution is the Special Needs Opportunity Windows or SNOW Project, an initiative funded through the Ontario Ministry of Education that is hosted and administered through the Adaptive Technology Resource Centre at the University of Toronto. The SNOW Project is an online provider of professional development opportunities and resources for educators and supporters of students with special needs. Using Web-based courseware tools, SNOW offers training and curriculum materials along with interactive discussion forums to assist Ontario educators in applying experience and strategies to benefit all learners.

Recognizing the need to support educational assistants, SNOW launched its In-service Development for Educational Assistants or IDEA workshop series in January 2001. The goal of the program was to provide educational assistants with the opportunity to receive training to support learners who have special needs. Covering a wide range of exceptionalities, the IDEA workshops are designed by experts in special education and feature moderators experienced in delivering distance education and are adept at creating an engaging and interactive learning environment.

Web-based training has inherent advantages compared to standard classroom training. For instance, SNOW workshops:

- Have anytime, anywhere access providing convenience for those who require a flexible schedule,

- Are developed using multiple file formats (text, images, audio and video) to support learning objectives across multiple platforms,
- Offer opportunities to perform investigative research and lateral learning in addition to the authored course content,
- Are offered in asynchronous formats so participants can choose when is most convenient for them to schedule their study time, and
- Afford participants the ability to communicate both with the instructor as well as peers to receive a broader base of knowledge and experiences.

IDEA workshops cover topics surrounding support for learners with autism, cerebral palsy, acquired brain injury, spina bifida, epilepsy, behaviour disorders and learning disabilities. The workshops are not restricted to educational assistants; anyone who works with learners who have special needs will benefit from these workshops.

The SNOW Project is funded by the Ontario Ministry of Education through the Provincial Schools Branch. For information on the SNOW Project and the IDEA workshop series, please visit http://snow.utoronto.ca/

Curriculum Coordinator for the SNOW Project

PRESENTATION TITLE

Motivate Others to Change: How to Accelerate Personal CHANGE-ability and Master Resistance!

LEARNING OBJECTIVES

As a result of attending this workshop, participants will be able to:

1. greatly enhance their personal ability to manage change;
2. more effectively influence others, including small and large groups, to change;
3. understand and manage the roots of resistance;
4. apply the practical tools needed to effect large-scale group change.

DESCRIPTION

This session will provide a provocative, cutting-edge approach to change that combines psychotherapeutic methods and in-depth experience helping employees through significant change. Provides a solid foundation and practical tools to enhance individual CHANGE-ability and successfully affect change in organizations.

The session explains the deep roots of resistance and provides practical tools to overcome it. Provides participative exercise to explore how the nature of change is significantly different than in the past, and why we must get much better at handling complexity and change. Participants learn the typical reactions to change and use a self-assessment to understand their **own** reactions. The session defines the secret formula for large group change and shows how the formula can be applied. There are hands-on group exercises that enable participants to employ tactics and strategies to help others through change.

BIOGRAPHICAL SKETCH

Peter Hess is the President of ***CHANGE Partners***, a Human Resource management consulting firm. With 20 years' business experience and a proven ability to achieve business goals through people, Peter has enabled clients to achieve bottom-line impact by better managing change, aligning corporate culture and strategy, and improving team effectiveness.

CHANGE Partners' clients include Pfizer, Bristol-Myers Squibb, Bayer Corp., Sterling Winthrop, Merck KGaA, Pharmacia Biotech, JP Morgan Chase, MetLife, Prudential, AT&T and Nabisco.

Peter has a BS in Psychology from Swarthmore College and a MS in Human Resource Management from Rutgers, and has taught classes for Rutgers, Columbia, NYU and the AMA.

OUTLINE

- ***The New Context for Change***
  - What can we learn about change from the great thinkers and doers, and how does this apply to our everyday lives?
  - Participative exercise to explore how our world in the '00's is significantly different, and implications for the need to get much better at handling complexity and change.
- **Awww, Do I Have To?**
  - Explains and illustrates the deep roots of resistance, and provides practical tools to overcome resistance.
  - Shows the three typical personal reactions to change and complexity, and provides a self-assessment participants can use to understand their own reactions.
- **Invigorating CHANGE-Ability**
  - Provides research and practical, real-world examples to help participants under the five paths to Change Mastery.
  - Participants work together to understand and apply the five paths to Change Mastery.
- **What Great Change Agents Do**
  - Defines the secret formula for large group (organization or community) change, and shows how the formula can be applied.
  - Hands-on small group exercise that enables participants to employ tactics and strategies to help others through change.
- **Energizing an Organization or Community**
  - Practical application of the seven stages of large group change.
  - Participants craft a customized Change Mastery Plan for their organization or community.

Best Practices in Blended eLearning

Presenters: Jennifer Hofmann, President, InSync Training Synergy, LLC
Gregory Dunkling, faculty, The University of Vermont

The efficacy of eLearning that has been demonstrated over the past few years through corporate training and higher education initiatives gives distance learning professionals great hope for the future of this educational and training medium. Yet there are significant obstacles to overcome before online education achieves the level of acceptance that many predicted it would just a few years ago. In this presentation we explore the use of blended eLearning, defined here as the use of asynchronous and synchronous Web delivery, focusing on research that we conducted over the summer of 2002 as we examined emerging best practices. We also explore whether these obstacles that are impeding the growth of online education can be addressed through the use of an appropriate mix of asynchronous and synchronous delivery.

Let us first examine the history of distance education. This brief timeline illustrates the changes that distance learning has undergone over the past two centuries:

- 1840 - 1st Correspondence study
- 1900's - Audio Recordings
- 1920's - Radio Stations
- 1930's -Television
- 1960's - Satellite
- 1980's - Fiber Optic/ Audio visual Tech/CD ROM
- 1990's to Present - World Wide Web

The introduction of each of these technologies brought with it the promise of a revolution in education. Some visionaries were even so bold as to declare that new distance learning technologies would supersede the traditional classroom. Indeed, after the invention of motion pictures in 1913, Thomas Edison asserted that:

"Books will soon be obsolete in the public schools. Scholars will be instructed through the eye. It is possible to teach every branch of human knowledge with the motion picture. Our school system will be completely changed inside of ten years."

While there have been some very enduring distance education enterprises, traditional classroom education is still by and far the norm. The failure of Edison's vision raises the question, "why hasn't distance education become more accepted?" The answer may lie in the way distance learning professionals approach content design. Instead of creating content that utilizes the most appropriate techniques for the instructional goals and is adapted to the latest technology, distance learning course developers (i.e. faculty and trainers) have historically taken the traditional classroom format, dropped it into the new technology, and waited for the technology to do the work.

At the Open Learning Conference in Brisbane, Australia in December 1998, Professor Peter Swannell, Vice-Chancellor of the University of Southern Queensland, commented on the infeasibility of this approach, emphatically asserting that, "Without a new pedagogy, the technology will fail."

With this realization, it is necessary to return to the current developments in eLearning. While most agree that eLearning holds much promise, there are still significant obstacles that must be overcome before this medium makes a profound impact on education and training.

Three of the most important challenges hindering the progress of eLearning development are: 1) how to develop quality educational content in cost-effective ways; 2) how to reduce the development time of quality eLearning content, and 3) how to maximize the learning experience of participants in online education by recognizing different learning styles and using an optimum balance of asynchronous and synchronous delivery.

Recent changes in both the online and traditional classroom paradigms point the way to the future. Dr. Roy Lundin of Queensland University of Technology in Australia, discussed the changing technologies and uses of synchronous and asynchronous delivery in education at the seventh annual Sloan Foundation Conference this past year. He finds that:

"With the introduction of various technologies, more particularly online technology, the face-to-face paradigm is giving way to an increase in asynchronous work being done through email, discussion groups/forums, and Web based activities. In contrast, the off-campus educational paradigm traditionally involved only asynchronous contact, firstly via correspondence lessons using print interactions, then some basic audiovisual components, including broadcast radio and television. This then gave way to the introduction of synchronous technologies. With these two major delivery paradigms now coming together the question arises whether there is an optimum balance between the need for synchronous and asynchronous interaction among teachers and learners."

Distance learning professionals working to develop eLearning programs, it seems, are drawing on changes that online technology now make possible.

The combination of work in higher education and the corporate training community offer interesting opportunities to learn from our collective experiences. For example, in the early-stage efforts to put training and education on the Web, colleges and universities focused on instructor-led asynchronous delivery while corporate training initiatives emphasized self-paced eLearning and some use of synchronous delivery. Yet both have been challenged by the need to keep learners engaged in their learning and ways to best accomplish this. Often, the worst of first wave eLearning was little more than eReading and Powerpoint with audio, while best uses incorporated a blending of asynchronous and synchronous delivery with strong instructional design. The disparity between the "worst" and "best" of eLearning was significant. Nevertheless, a convergence of best practices is beginning to emerge. This growing knowledge-base and cross-fertilization between formerly disparate eLearning efforts in higher education and corporate training will help provide answers to how to best design fast, affordable and high quality online educational content.

In July, 2002, we launched a survey entitled "Best Practices in Blended eLearning," to look at how organizations are implementing distance learning, with special focus on instructional approaches that have contributed to quality programs. Certain survey respondents are being selected for follow up interviews based on the success stories and problems they described in their responses. Our goal is to establish examples of best practices in blended eLearning solutions. We asked respondents to comment on issues and trends in several categories, including:

1. **Technology blends.** Taking a look at what technology is being used in the Best Practices scenarios is critical. While there are many excellent examples of eLearning programs that only utilize one technology, the appropriate blending of technologies seems to lend itself to better participant retention and appeals to more learning styles. Cracking the code to discover some of the best technology mixes was a critical goal of our research.

2. **Change management techniques**. As the Internet and its related technologies mature, educational tools become easier to use for content development and delivery. In fact, implementation of eLearning in an organization is often more of a change management initiative than a technology implementation. We wanted to know what change management techniques were being employed in these initiatives to get the buy-in from the organization, prepare teachers to teach, and help students learn. We also investigated the successes and failures of new eLearning initiatives that did not have change management components.

3. **Design strategies and development techniques.** The success of eLearning programs is often determined by the quality of the instructional design. We identified the key questions that must be addressed to ensure that design matches content: What types of performance objectives are being delivered successfully through the different technologies? What is the most appropriate media? How much interaction is required? How do you keep your audience engaged? How do you know if they are learning?

As with any new trend, the possibilities and pitfalls of eLearning technologies are not yet fully realized – and probably will not be for some time to come. Training and education professionals are creating their own best practices as they go along – best practices that may have a very short shelf-life, as it will not be long before we can improve on them. During this early stage of synchronous development, effective implementation will only be realized through prudent and conscientious development to create the right settings and learning environments. Content must also be well designed, blending the most appropriate delivery methods. eLearning seems to be here to stay; but its impact on education remains to be seen. Through thoughtful planning to ensure that the quality of instruction meets or exceeds the classroom experience, however, it may be a welcome alternative to traditional pedagogical formats.

In this interactive presentation, we will report our findings on the recent survey of American colleges and corporations exploring the effective use of blended learning solutions. Participants will be encouraged to contribute by bringing their own research or experiences to our discussion of best practices in blended eLearning.

Interactive Session Description

Title – ***Best Practices in Blended eLearning***

Based on the results of the "Best Practices in Blended eLearning," this interactive session is designed to allow eLearning practitioners to learn about best practices in blended eLearning and provide a forum to exchange ideas and share their own experiences. Participant input will be documented and made available after the session. A paper describing our findings from this research will also be made available for attendees.

Session Objectives

In this session we will:

- Review the structure of our survey
- Report on research findings
- Facilitate a discuss around the reaction to the research findings
- Exchange best practices and encountered problems.

Intended Audience

This presentation is intended for experienced practitioners in the eLearning field. Attendees should have been involved in the design, development, delivery, or implementation of several eLearning programs. Participants should be familiar with examples of asynchronous and synchronous delivery software.

Online Professional Development in Instructional Technology: Star-Online

Patty LeBlanc, Ph.D.
Department of Education, Stetson University USA
pleblanc@stetson.edu

Ms. Angelique Lewis Nasah, M.A.
Bethune-Cookman College
nasaha@cookman.edu

Abstract: This interactive session will demonstrate an online package used at Stetson University and Bethune-Cookman College with faculty, students, and K-12 partnership teachers for professional development and growth. In addition to demonstrating Star-Online, the presenters will describe how it is used for professional development at the two institutions and the results of their use at the college/university and K-12 levels. Participants will be encouraged to "test-drive" a module to determine whether they might be useful in their work environments.

E-Learning

E-learning has been described as "the use of technology to design, deliver, select, administer, support, and extend learning" (American Society for Training & Development, 2000). The power of the Internet as an e-learning delivery system is in its ability to increase personalized, individualized learning to meet the learner's interests, skills, and needs at that particular time. In e-learning, the learner is allowed to actively construct his/her learning in a way that meets his/her needs and learning styles.

A number of commercial and government providers have developed and marketed outstanding training/learning materials to be delivered online to business, government, and private sector employees in an effort to provide "anytime, anywhere learning" available, for a fee, to anyone who has access to a computer and the Internet. Key elements of this type of learning and delivery method include:

- An extensive library of coursework for user selection;
- Focus on adult learners and adult learning theory;
- Authentic, practical learning that is engaging to the user;
- Assessment of skill development and progress, including pre-tests that allow the user to personalize his/her learning path;
- Outstanding instructional design;
- Mentoring and collaboration capabilities as needed;
- Supplemental resources for the user to extend learning.

Stetson University and Bethune-Cookman College are part of a consortium funded by the U.S. Department of Education's PT3 initiative to prepare prospective teachers and university faculty to use technology effectively to achieve instructional goals. One of the capacity building efforts of the third and final year of the PT3 project was to find web-based solutions for technology skill and integration training which could be accessed anytime, anywhere. A comprehensive examination of a number of *just-in-time* technology training systems revealed that there are many outstanding web-based products on the market today. Many of the products demonstrated exemplary instructional design and included each of the key elements mentioned above. However, we felt that Star-Online best met the training needs of the PT3 project goals and was the most cost effective product reviewed.

This interactive session will demonstrate Star-Online and how it is used at Stetson University and Bethune-Cookman College with faculty, students, and K-12 partnership teachers for professional development and growth. The presenters will describe its utility for professional development and the results of its use at the college/university and K-12 levels. Participants will be encouraged to "test-drive" a module to determine whether Star-Online might be useful in their work environments.

Star-Online

Star-Online was produced by the United Star Distance Learning Consortium (USDLC) as part of its *Anytime, Anywhere* grant funded by the U.S. Department of Education. Star-Online in an inexpensive, but sophisticated resource for pre-service, new, and veteran teachers that provides training, support, and communication links to facilitate the effective use of instructional technology to enhance teaching and learning. Teachers can access mentors, colleagues, and resources via its web-based Virtual Teaching and Learning Community (VTLC). STAR-Online (Supporting Teachers with Anytime/Anyplace Resources) recently received top ratings recently in eSchool News' online Readers' Choice Awards for best training solution (Edmin, 2001). It placed third in the category of Professional Development Management Tools and fifth in Curriculum Integration Tools in a comprehensive review of training and delivery models for educators.

The components of the Star-Online program include:

- 32 online modules on use of technology in the classroom, emphasizing both skill-based training and application of newly learned skills to educational settings;
- Assessment systems that include a pre-survey for individual self-assessment of needs, which results in an individualized staff development plan;
- Differentiated instruction based on the operating systems used by participants;
- Individualized, online portfolios for teachers to access module status, technology survey results, competencies, activities, lessons, and results from modules;
- Feedback from expert reviewers at Star-Online regarding individual progress;
- Reports for schools/districts to assess need, use, and effectiveness of the online training;
- Online support to teachers, as well as to mentors and technology/staff development planners;
- Online resources with links to relevant sites;
- Online communication tools (chat room, listserv, and bulletin board) for networking.

Each of the 32 staff development modules is self-paced, includes the same components, and has the same common user interface:

- competencies that correlate to ISTE's technology standards for teachers,
- interactive lessons,
- application activities,
- integration ideas,
- sharing,
- evaluation.

Using PT3 grant funds, a site license for Star-Online was purchased for use at Stetson, Bethune-Cookman, and Bonner Elementary in Daytona Beach area in central Florida. The modules and support systems in Star-Online were used during the summer by K-12 teachers as a pilot to determine their effectiveness, and will be used during the 2002-03 academic year as part of the grant's capacity building efforts. Pilot data revealed that every teacher (n=30) who used the modules rated them as excellent learning tools and very useful for developing both skills and ideas on how to integrate technology effectively in their specific work environments.

This fall, Star-Online will be used in a variety of settings: 1) faculty members in Teacher Education and the College of Arts and Sciences will use the modules for their own professional growth in the area of technology integration, 2) pre-service teacher education majors will be using the modules as part of their coursework assignments, and 3) teachers at the partnership school, Bonner Elementary, will use the modules in true anytime, anywhere fashion as part of their efforts to increase their proficiency and comfort with technology. Star-Online's performance-based assessment portfolio and the products created make it easy to quantify the level of use and whether or not the student or teacher has achieved mastery of the module topic. Those who use the modules have been asked to evaluate each one and provide feedback to the project director, who will analyze the results of use at the end of the each term in the 2002-2003 academic year.

Time will be given during this interactive session for participants to review the Star-Online modules and ask questions.

Abstract: The "Rule of Thirds in Photography" is a Macromedia flash-based program which aids learners in becoming visual literate through the introduction of design principles and compositional techniques emphasizing the Rule of Thirds. The product uses multimedia activities addressing the special needs of English as a Second Language learners in the realm of photograph composition. Produced for Communication Technology students at the Higher Colleges of Technology in the United Arab Emirates, this product uses highly graphic culturally and geographically reflective course materials and exploits Flash's interactive environment. This paper presents a plan to evaluate the "Rule of Thirds" multimedia software which was developed by the authors.

Introduction

The students in the Communication Technology program at the Higher Colleges of Technology (HCT) in United Arab Emirates graduate with a Diploma after three years in the College Program. Teachers recognize that although the students are highly technology savvy and have grown up in a world where visuals are a prominent part of their life, the students have done very little interpretation, analysis, critical review of the visuals invading their lives. The instructors know that for the students to be successful in the program, they need to become visually literate. There are many courses through their three years that work at improving the students' visual analysis skills and there are several instructional methods used. This proposal looks at using multimedia as one method of teaching pertinent visual skills.

In the first year of study in the Communication Technology program, not only do the students learn about Graphic Design, Journalism and Video Production (the three fields they can later specialize in) but the foundation is also set for them to become better visual communicators. One first year course, Visual Communication I, is paramount to the students achieving good results in their future specialization. The course has a large hands-on component where the students complete over 12 projects during the 14 week semester. Through these projects the students develop a more critical view of their work, their peers' and professional work. Recognized by both teachers and students as one of the key courses in year one, the course promotes reflective thinking concerning graphic design, photography, video and other visual content.

BEST COPY AVAILABLE

One part of the Visual Communication course teaches the students the Rule of Thirds. It is found specifically in Goal #2, Objective #2 which states:

> ***GOAL #2** - The student will demonstrate good compositional techniques in the production of a variety of images.*
>
> ***Objective #2** - Identify and apply the elements of composition (Point of View, Rule of Thirds , Framing, and Perspective) in the production of images*

The Rule of Thirds is a well known photographic compositional technique but surprisingly, it can be traced back to Greek times where it is known in its original form as the Golden Mean. Basically, the idea presented in the Rule of Thirds is that you should not put a subject in the middle of a photo but rather, it is most pleasing to our eye to have it along an imaginary line that divides the photo in thirds either horizontally or vertically.

Rule of Thirds Software Background

The "Rule of Thirds in Photography" software was developed by the authors as part of the "Quality in Teaching and Learning" professional development program at HCT. Although not expected to replace the instructor, the software has been developed for students to use on their own in a self-learning mode. As a follow up, it is expected that the students would complete a 'real world' photography shooting assignment where they would apply the rule of thirds to their own photography.

At the completion of the thirty to forty-five minute computer-based training program, the software suggests that the student will be able to:

1. Choose the main focal point of a photo or identify photos that do not have a focal point.
2. Explain the terms focal point and composition.
3. Explain what the Rule of Thirds means and why a good photographer might use it.
4. Show how the Rule of Thirds can be used when composing photos.
5. Identify photos which use the Rule of Thirds from those that don't

The software is organized in this way:

1. Learn about focal points
2. Create a focal point
3. Focal points vs. Centre of Photos
4. Introduction of the Rule Of Thirds
5. Rule Of Thirds Activity
6. Summary
7. Quiz

The Study

This study will look at the use of multimedia to teach the Rule of Thirds, as well as other compositional techniques. Currently, the Rule of Thirds is introduced in a classroom setting where the students review photos (professionals and their own) and apply the rule, while discussing its implications; next the students would complete a hands-on assignment where they shoot photographs that reflect the Rule of Thirds. This study will alter the lesson somewhat, in that the in-class session will be replaced with 'technology' – the multimedia software to be tested. The discussion about the Rule of Thirds and the assignment will still occur, with both happening when the students hand in their photo assignment.

In particular, the study will investigate (1) WHAT students are learning about the Rule of Thirds and photography in general; and (2) HOW students learn about the Rule of Thirds using technology. Some of the outcomes we are particularly interested in include:

1. We want to know if the students ....

  - Will learn the "Rule of Thirds" – as in, can they recite it and demonstrate how a photo follows the rule.
  - Will begin to use a new way to talk about photos, essentially incorporating some of the, terms, style and content introduced on the Test Software.
  - Will talk about the Rule of Thirds and/or other compositional techniques as expressed in the Test Software, when describing their own photos or their peer's photos.

2. Does the software hinder their learning in any way? Are there features that they found annoying or frustrating or ones they didn't understand?
3. What features did the students feel helped them the most to learn the Rule of Thirds or other compositional techniques?
4. Do the students afford themselves of the various learning opportunities the software developers believe they have included in the Software?
5. We will ask the students what they feel they learned from the Test Software.
6. When going through the software to learn the rule of Thirds, (usually an individual process) will the students change the learning environment into a more social one, where they will share with each other what they find as they go through the product?

Evaluation Plan

In order to discover *(1) WHAT students are learning about the Rule of Thirds and photography in general; and (2) HOW students learn about the Rule of Thirds using technology*, we have devised a plan that includes such items as video captures of the screen while students use the software, classroom videos of the students using the software, focus group feedback sessions by the students as well as individual interviews. A web-based feedback form will be in operation throughout the evaluation period for other classes throughout the HCT system to use and assess the software.

At the same time that the students' feedback is sought, there will also be a strong attempt to acquire responses about the software from a variety of significant sources. In particular we will also be compiling observations from all the teachers who use the concerning administering the software, software content, usability and what features of the software they believe that their students learned best from. As well, software evaluation, photography and multimedia experts will be asked for feedback on both the evaluation process and the software product itself. We are planning to attend several international conferences throughout the year to present the software and get feedback from our peers in our industry. One such conference is the Association for the Advancement of Computing in Education E-learn Conference in Montreal, Canada, 2002 where we are presenting an Interactive Session.

Anticipated Outcomes

It is expected that with the amount of feedback and assessments we have planned for the product there will be ongoing development work of the software throughout the year. We expect to receive many good suggestions about how to improve the product and we intend to follow through to ensure we have a top-quality product.

This study will investigate two main questions: (1) WHAT are students learning about the Rule of Thirds and photography in general; and (2) HOW are students learning about the Rule of Thirds using technology. It is anticipated that the students will definitely learn the Rule of Thirds from the software. It is an easy concept to grasp as reflected in the many simple websites that present the idea. So the greater interest is - how much of the 'other' compositional techniques included within the software will be added to the students' 'visual tool bag'. It is anticipated that what else the students learn from the software will be a function of what they bring to the software. Students who have shown a keen interest in the visual arts will pick up and adopt more of the "other" information included in the software. Although this finding won't be a surprise, it will emphasize the importance of nesting more advanced terms/ideas (compositional techniques) within a simplerone (the Rule of Thirds).

Outline for Interactive Session

A standards based math program developed by classroom teachers has resulted in 30 student modules that are customized, Internet based, and video enhanced.

1. Overview - Objectives

Participants will:

- view and interact with a Professional Development module and experience one student module with its interactive, video, gaming components

- receive information on a proven process that has been successful for districts receiving millions in technology awards; used by a consortium of 6 school districts to build a technology rich middle school mathematics curriculum that is standards based; process has been replicated for other technology initiatives among school districts

- articulate the process of consortium building and developmental stages of "break-through thinking" in designing a customized multi-media, Internet delivered curriculum for diverse student populations for middle school mathematics

- have information as how to access the eMath Project with 30 math modules as funded by a $1.8 million TIE Grant from the Texas Education Agency; how to participate in on-going research of the impact of emerging technology in mathematics education

- experience one teacher's journey in break-through thinking on developing the mathematics modules for grades 6-8

2. Outline of Presentation

- Review 3 years of planning, goal setting, defining needs by 6 school districts
- Discussion of teacher input, curriculum design, break-through thinking in process of designing the curriculum;
- Outline of the design of the web-based content to support the original video clips used in the modules with a thematic and problems based approach

Audience will experience photos of teachers in the development process, see examples of modules that teachers have developed, view a video clip of administrators discussing the support given to the project; experience a module (as though they are students) to solve the posed problem and work toward solutions with web-based and a gaming activity.

3. Research Based — Because this project is cutting edge of emerging technology curriculum development, an Expert Panel of nationally known math professors was engaged through TEXAS A&M University to write a 'White Paper" on best practices in middle school technology initiatives in mathematics. The research is embedded in a staff development module.

4. Presenter Qualifications—In past 9 years the presenter has received funds for nearly $22 million for technology initiatives for consortiums of Texas schools, all the while serving as assistant superintendent for curriculum or acting as project director. Served on the 1999-01 Texas Education Agency Educational Technology Advisory Committee. The eMath Project is a first in the area of convergent media that uses both video and interactive web-content and delivery. This pilot for six school districts with 85 middle school math teachers and 6,000 students is being carefully followed in Texas for its impact of delivery of mathematics in the future.

5. Co-presenter—is a Research Scientist in the College of Education, Texas A&M University, College Station, Texas. Dr. Jolly is known nationally for being involved in the development as well as research of technology rich projects from Kindergarten to the post-secondary levels. The eMath Project is being evaluated from a "legacy issue" basis to determine the process that teachers must engage in as part of restructuring the delivery of curriculum that is integrated and cross-disciplinary.

   - Workshop appropriate because it represents a major effort to integrate emerging technologies into the middle school math program; uses teacher expertise in designing the content and delivery system
   - The hand-on presentation will provide participants an opportunity to experience cutting-edge mathematics that teachers and students will have access to in the near future throughout the State of Texas
   - Major Presenter has given presentations to local, state, national, international audiences on technology, school reform, staff development for past 15 years; Co-presenter is known nationally for research and evaluation of cutting-edge projects
   - The eMath Program of 30 modules will be presented and how other districts can access the federally funded (TIE) initiative

Community Capacity Building with an E-Learning Strategy

Connect New Brunswick focuses on "engaging' entry level computer users in individual or small group setting. Connect New Brunswick Community Computer Access Network staff deliver grassroots programs to attract people to the onramp for the information highway. It is critical that citizens that have worked in our more traditional jobs have "access" to computers, skills training and confidence building opportunities, in their communities, so they to can participate in the economy with the required skills training as they did when they supported and drove the old economy!!

This session will include an overview of this community - based network and profile its E-Learning strategy and resources for supporting these entry-level learners.

Communities can't exist without jobs and employers can't exist without an employable workforce. Community Capacity building is sustainable with a "Hand up" rather than a "Hand out" therefore, consideration of an entry-level program should be the first step in any E-Learning strategy!!!

E-Learning initiatives of Connect NB Branché:

The following programs have been developed/utilized by CNBB for delivery in Community Access Centres. Their dual mandate is to meet the training needs identified throughout rural New Brunswick as well as generate a revenue stream to support the sustainability goals of the Centre.

Each program is supported with resources online to standardize program implementation and delivery. In addition, a network of Regional Liaisons that work directly with centre employees is mandated to monitor these training protocols with new and current staff as each new program is developed.

Programs include:

GED-Training Online- Connect NB Branché provides "Virtual Mentor' supported online training for GED clients throughout New Brunswick at access centres in communities where the clients live! Connect New Brunswick is the first in North America to provide this service to our citizens with an outstanding success rate to date.

Policy 701 Online- Connect New Brunswick developed this bilingual program to support the standardized delivery and validation of the compulsory Dept. of Education Policy 701 training for Access Centre Staff and volunteers. In addition, the Dept. of Education officials for support to Administrators validated the resource in the public school system. The website is maintained by CNBB staff and materials have been distributed throughout the province.

IntroNet Online - This bilingual online training program was developed by Connect NB Branché and Industry Canada as an introduction to the Internet and is utilized by Access Centres throughout New Brunswick to support the training and sustainability goals of the centres. Trainer Resource Materials and course access are available at all centres via password.

QuicClics- This bilingual online training program has been developed to utilize the concept of *Train the Trainer* to prepare 1-½ hour courses for all 250-centre staff to offer in their centres for revenue generation. Each course is supported by all the necessary presentation material from power point presentations to certificates of completion, and with lesson plans, handouts and evaluation forms to name a few. Each employee can be trained online ready for program implementation in a 2 week period on any program we design!!
Programs include:
Basic "10 slide" PowerPoint
Managing your Internet History File
Drag and drop File Management
Basic Scanning
Digital Camera Basics
BoaterExam.Com Supervision protocols
Abuse Prevention Protocol
CyberSafety

Microsoft Office Computer Based Training Program- Connect NB Branché purchased this CD ROM based training tool from EduPerformance Ltd. (French version) and Mentor Networks (English version) to support the advanced training needs of citizens in rural communities where other options may not be available. The service also supported the sustainability goals of the Centre.

BEST COPY AVAILABLE

Reader Rabbit Series- Each Centre has been provided this CD Rom training series for children at the Toddler, Pre School, and Kindergarten levels to support learning strategies and content for children at these age levels. The service is free.

Brunnet Training Courses- Each centre has access to password controlled introductory and advances, unfacilitated courses online from any Centre in our province. The intent of this partnership is to extend online training opportunities utilizing over 300 online courses while revenue splitting with the partner to support the sustainability of access centres. Securing a partnership with a similar Francophone course provider is in the works.

Cybersafty – A 2 ½ hour online "information" program designed for parents and teachers to understand the not so common knowledge about monitoring children on the Internet. This informative program was developed in partnership with Telephone Pioneers International and the RCMP.

Abuse Prevention Protocol – A two-hour personal look at abuse and its recognition and prevention for parents and professionals. Topics are sensitive in nature and require a mature perspective. Content was recently released and piloted with Sport Coaches and Youth Camp Counselors. Full delivery is in its formative stage.

Regional Liaison Program- Connect NB Branché has developed a bilingual training model to support the skill development of Centre workers and volunteers. The intent is to standardize the skills of workers in centres and familiarize them with the delivery standards required for programs offered by the centres for citizens in the community. Individual instruction plans are developed by one of our 10 Regional Training Assistants utilizing several assessment tools. A complete training guide has been developed to guide this model.

CNBB Resume'

In 1995-96, the Province of New Brunswick, in partnership with Industry Canada, NBTel and the Department of Education, successfully piloted the first six electronic Community Access Centres in Canada providing rural citizens with public access to the information highway. From this pilot evolved a national initiative by Industry Canada called the Community Access Program (CAP).

In 1996, recognizing the future potential of providing New Brunswick citizens with affordable access to the information highway, Connect NB Branché was formed as an operating agency of the Information Highway Secretariat and Economic Development, Tourism and Culture. The Community Access Program (CAP) is supported by and maintained through a partnership with the Industry Canada, the Province of New Brunswick, NB Tel and a network of over 200 volunteer community steering committees representing over 400 communities. Connect NB Branché's role was to assist these communities in developing their own locally managed and operated public Access Centres to meet the following objectives:

- To provide New Brunswick with more affordable access to computer technology and the Internet and to raise awareness about its potential for learning, jobs and growth;
- To stimulate the use of new electronic learning tools to further develop services by and for all New Brunswick communities;
- To provide Internet and World Wide Web training facilities for local entrepreneurs, employees, educators, students and others interested in improving their information management and networking skills;
- To stimulate access to the electronic delivery of government and other services and obtain feedback from citizens about how they would like these presented.

In order for Connect NB Branché and the Community Access Centre Network to realize these objectives. it had to embrace the following direction:

- VISION – To establish partnerships with and for communities to further their economic, cultural, and social development regionally and nationally.
- MISSION – To provide citizens of New Brunswick with lifelong learning opportunities utilizing current information technologies in an accessible community environment.
- MANDATE – To establish and provide sustainable support to Community Access Centres in all locations throughout New Brunswick.

Today, Connect NB Branché and the province of New Brunswick are recognized as a world leader in providing its citizens with access to information technologies and on-line opportunities in a community environment.

A. 1999-2002 Statistical Brief

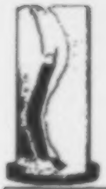
230 Community Access Centres in New Brunswick
    132 English 98 French
    153 in schools 77 in other locations
300,000+ visitations to Community Access Centres
221,000 hours of public access provided
250,000 hours of volunteer assistance contributed annually
1,928 courses offered
20,760 people took training
426 persons hired to work in Centres facilitated by CNBB
63% of Social Assistance Recipients found work after 6 month work practicum in Centres
826 individuals found jobs or economic benefits through Centres
200+ "good news" stories published in NB newspapers
16 International delegations visited
3 Countries contracted with CNBB for support

B. Major Accomplishments, Human Resource Assets, Contractual Agreements

I. ***Accomplishments***

1998 National Information Technology Awards winner of the Distinction Award for ***"Cross Jurisdictional Cooperation"*** *(Federal – Provincial) in the management of information and technologies in the public sector*

1998 GTEC Silver Meda



2000 National Award winner of the Conference Board of Canada Award for **"Broad Community Collaboration"**

Conference Board 2000

3. 2001 CANARIE National "IWAY" Award Winners in the category "Application of Technology"

E-learning in Spanish: a Language and Culture Course and a Placement Test

Jessica Payeras and Evelyne Diabaté
École de langues
Université du Québec à Montréal
Canada
payeras.jessica@uqam.ca

Abstract This paper presents two projects that make full use of WebCT in the Spanish language department of the University of Quebec at Montreal. These projects are: a Spanish language & culture course and a Spanish language placement test. With respect to the culture and civilization course, we shall focus in three specific aspects: the communication and collaboration tools, assessment tools and varied content release. The communication component includes the possibility of using Discussions, Chat, Whiteboard, and Mail. The evaluation tools include self-tests, surveys, and quizzes with a variety of question types, giving instructors unlimited flexibility in how they choose to incorporate assessments into their courses. The selective content release allows instructors to create content modules or assessments and selectively release them to individuals or to groups, based on a variety of parameters, such as time or student performance.

Introduction

The literature on computer-assisted language learning indicates that language learners have generally positive attitudes towards using computers in language testing. This view is expressed in a large bibliography, including the following studies: Alderson, Clapham and Wall (1995) and Bachman (1990). From a manually corrected placement test, we decided to switch to a computer-based placement test using the WebCT platform. WebCT is a global market-leading course management system. With a complete set of easy-to-use teaching and learning tools for course development, course delivery and course administration, WebCT was the best choice available in the market for our specific needs. WebCT empowers institutions with the ability to serve broader student populations and offer flexible learning opportunities to meet diverse student and administrator needs as we shall see in this interactive session. WebCT also provides a comprehensive set of options for accessing, managing, and migrating course content. Instructors have the unique ability to direct and pace the learning experience based on time or student performance parameters. We present in this presentation the two projects in our department: the language and culture course and the placement test.

The language culture course

The language course stems out from a joint effort between the History department and our department in order to produce a Web site that could be used in conjunction with the culture course. An electronic version of the Culture course was created with the HTML format. Special care went into the design of the sections and the links (see Figure 1). In addition, grammar exercises were incorporated in the PDF format to allow students to print out pages and do these assignments at home on a voluntary basis. Even though the appearance of the course was very appealing to the eye, we were sure that we could make it much more efficient including links to help them with their research topics, a virtual dictionary and all the communications components such as the e-mail and chat services. The course design comprises the following elements: the course description, an interactive calendar that allows students to customize information according to their needs, the complete text book in html

BEST COPY AVAILABLE

format, the multimedia workshops, a power point presentation of the grammar content, grammar notes, links to web pages related to the contents of the course, an on-line dictionary, an individual and private link to each student's grades, a communications component (e-mail, forum and chat limited to the class students and the teacher), a basic grammar quiz to verify the entry level and a separate links that allows students to download the latest version of programs that might be needed such as WinZip, Acrobat Reader, etc. The main window of the virtual culture textbook can be observed in the Figure 1, below.

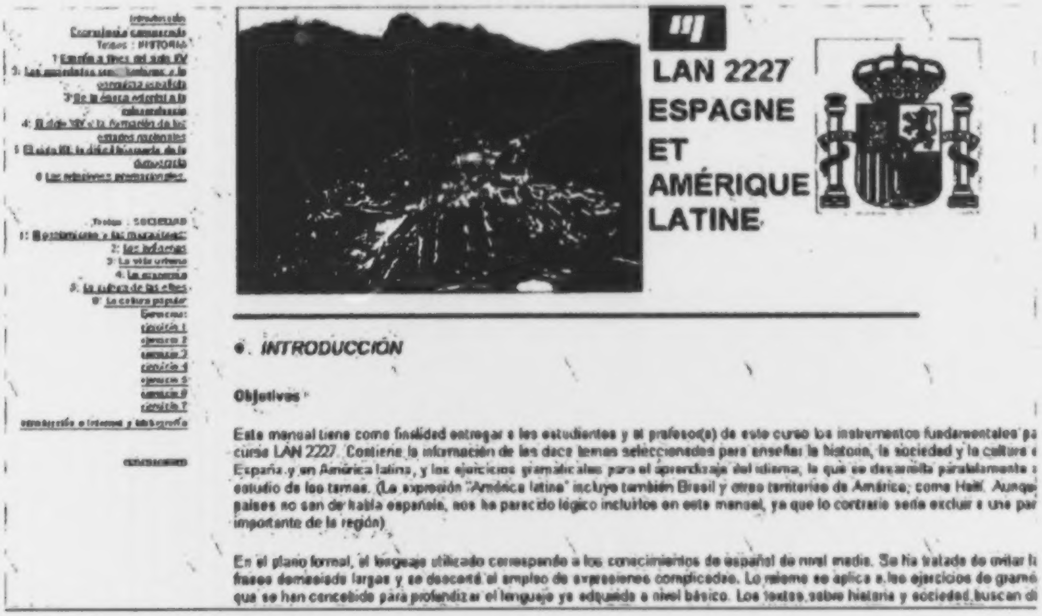

Figure 1: The language and culture course

The language placement test

Taking into account the versatility that WebCT had allowed in the virtual classroom production, the next project was the placement test. Up to that point the Spanish language department had only a written test that took considerable time to correct and a laboratory technician who had the task of distributed the paper version and collecting it at the end of the 60-minute limit. Several obvious problems were encountered with this option: unnecessary photocopying costs, impossibility of testing students with a different language capacity or different areas of language competence (reading comprehension, writing, listening, etc) and the time spent in the tedious manual correction oh each copy. To resolve all these problems, 3 different versions of the placement tests were developed: an basic, intermediate and advanced test in order to better evaluate a candidate's language ability.

One of the most robust component of the WebCT architecture are the evaluation tools. These include self-tests, surveys, and quizzes with a variety of question types, giving instructors unlimited flexibility in how they choose to incorporate assessments into their courses. Creating separate version of the test, much in the same as different courses, the students could be evaluated, have their tests corrected automatically and even have the opportunity to secure an inscription with a link to the Registration office. This option was very welcoming from the students' part and from the institution because the administrative costs and time usually involved in these operations were cut almost by 90%. Apart from all these advantages, different types of questions could be incorporated into the placement test: multiple choice, fill in the blanks, open questions and matching columns A to B. Images and sounds made the test more powerful. With all these options, new sections could be much more easily be evaluated: listening and reading comprehension, spelling and writing. With this tools, we could also

make an instant analysis of the questions were the most difficult ones to answer and obtain graphics that compared the individual scores to the scores of the whole group that sat for the placement test. Figure 2, below, shows what the placement test looks like:

Patricia____muy alta y delgada.

○ 1. estoy
○ 2. está
○ 3. es
○ 4. eres

Figure 2: The language placement test

Conclusions

After careful analysis of the students' responses, we were able to have a very important feedback from the students' part. We are extremely pleased with the advantages that this technology offers In a rather direct way, WebCT has allowed to offer new, compelling ways for faculty and students to engage in a process of teaching and learning that is interactive, of relatively simple utilization and able to reach "virtual communities" without any physical border. This created an e-learning environment where everyone can participate: students, teaching assistants, administrators and institutions as a whole. Among the most significant advantages, WebCT has enabled e-learning in Spanish at our department.

Exploring Science Education Using Handheld Computers and Data Collection Tools

Raymond M. Rose
Concord Consortium
United States of America
ray@concord..org

Abstract Small inexpensive handheld computers could play an important role in education in the next decade. They pose a way to address the digital divide. But they also offer more applicability for some of the advantages they bring to general computer use. One significant development, Smart Probes, could be the launching point for a whole new set of handheld applications. Concord Consortium has been developing the smart probe concept with help from NSF. These, the next generation of data collectors could lead the way in changing the way students experience science.

In the rush to bring modern information technologies into schools, one group of technologies is being overlooked that can greatly improve learning. While current desktop computer and network technologies are beginning to realize the huge impact they could have on education, other extremely valuable information technologies are not being used or even being considered.

Small, inexpensive, **handheld computers** and their associated communications channels and software tools could play an important role in education. The computational power and communications capacities of handhelds are increasingly impressive. Many pack the raw computer power of desktop computers only few years old while having increasingly good communication channels, either through a wired cradle, infrared beams, or radio frequency radiation. These channels can be used with software tools for a broad range of sophisticated productivity and browser applications. These handheld technologies could greatly enhance learning in and out of schools.

Yet, this *"anytime, anywhere"* computing goes beyond just handheld computers. Ubiquitous, mobile devices such as phones, wrist bands, wearable devices and intelligent structures are bound to impact the future of education.

Bob Tinker, President, The Concord Consortium (http://usight.concord.org/what/)

Concord Consortium sees the small portable handheld computers as an ideal platform to connect sensors. Seven years ago we began experimenting with a number of configurations of portable computers as part of our NSF funded Scinece Learning in Context project. We started with Newton and eMate computers but as they were removed from the market a new plan evolved. We have done a lot of work with Palm computers, but have developed out new probes and software to be platform independent. We refer to these new sensors as Smart Probes.

Smart Probes

We believe that field-based data gathering is an important facet of student learning and the handheld provides the power and portability to make that a reality. But in going outside, we've found that it is important to take the fewest possible numbers of parts and wires. Extra interfaces or wires are all that more to set up on site and tend to get lost. A real-time graph is often essential, too, to allow students to see their dataset as it is collected. Ideally, the probe is part of the graphing display

device. As a practical matter, however, it is probably cheaper to have one that simply plugs in and can be reused with other computers back in the lab.

Complete microcomputers on a chip now cost under a dollar. This means that they can easily be incorporated into a sensor, making it a *smart* sensor. At very least, a smart sensor can have information about itself that it sends to any computer it attaches to. It can tell what kind of sensor it is, how accurate it is, and when it was last calibrated. It can also contain its calibration information and report its values using physical units like degrees, Newtons, or Joules. This saves the host computer from converting from the usual "raw data" inputs and also greatly simplifies classroom management. In the traditional model of data sensors, calibration data are stored on disk and are different for each probe. To avoid re-calibrating each time the sensor is used, the sensors need to be matched to the computer containing the latest calibration data. Not so with a smart probe that carries its own calibration. The smart probe is always ready, all it needs is to be connected to the computer.

Smart probes with calibration, other information, and physical outputs may not be revolutionary, but they certainly would be useful for a very small additional cost. In fact, the cost may be negligible, since the microprocessor that provides the "smarts" can also replace other electronics needed in "dumb" sensors. But the usability factor is something that is hard to put a price to. Smart Probes offer a convenience to teachers that far out weight any cost differential. The probes use very little power and are most frequently powered by the devices they connect to. The low power consumption means the smart probes are normally ready to be used even after sitting for months on a storage shelf. They are also unlikely to run out of power in the field in the middle of an experiment.

As a result of funding from a number of NSF projects we have developed CCProbe (http://www.concord.org/ccprobeware/ccprobe/ccprobe.html) and currently have 5 data sensors that are being tested in the NSF funded Technology Enhanced Elementary and Middle School Science. (http://www.concord.org/teemss/). The specific TEEMSS sensors are:

- fast response thermocouple temperature probe
- force probe (includes a detachable magnetic field sensor)
- smart wheel (0.5 degree angular resolution, max linear speed 5 m/s)
- voltage and current (watt and joule meter)
- light probe

The research plans for the TEEMSS project include both evaluation of the goal of the project: student learning of the science concepts, and also of the components of the project: the units, materials, and teacher training. That research has not yet been completed but commercial vendors have expressed interest in both CCProbe and some of the SmartProbes.

Learner's Lounge: Information Brokering for the Adaptive Learning Environment

Marcus Specht, Milos Kravcik, Leonid Pesin
Fraunhofer Institute for Applied Information Technology FIT- ICON
{specht, kravcik, pesin} @ fit.fraunhofer.de

Roland Klemke
bureau42 GmbH,
roland.klemke@bureau42.de

ABSTRACT

This paper describes extensions of the Adaptive Learning Environment (ALE) [3] for web-based authoring and learning. The system provides a new methodological approach to design education on the web. ALE is used to build a large knowledge base supporting Architecture and Civil Engineering Design Courses and to experiment a comprehensive Virtual University of Architecture and Engineering Design in the project WINDS. The system combines classical structuring of learning materials based on reusable and sharable learning objects with and indexing approach for browsing the learning materials based on a alternative structure called the course index. The course index is a collection of important concepts for a course subject or a whole domain. By the combination of the course index with an information brokering software we were able to introduce new features focusing on the integration of highly dynamic content into courseware and enabling organizations to build fast changing and highly dynamic learning communities with coaching and tutoring facilities.

Keywords

Web based learning, educational hypermedia, interactive learning environment, adaptive systems, e-Learning, information brokering, educational brokering

Introduction

In the recent developments of e-learning aspects of skill management and the integration of fast changing knowledge became more and more important. From our point of view especially the production of content for flexible delivery and the easy integration of reusable learning objects in personalized courseware is a key point concerning usability and acceptance of learning management systems (LMS) in organizations. In the last two years in the European project WINDS[1] Fraunhofer FIT developed a new LMS focusing on simple authoring tools for the production of highly reusable content. Currently we have released a version 1.2 of the ALE system and 21 european university partners prepare more than 20 on-line courses that should be used by students from october 2002. For reaching those goals we have taken into account several of the existing standards and semi standards on learning objects, learner models and their storage and exchange for example [4, 5]. We can build on our experience with development of adaptive hypermedia environments like ISIS-Tutor [6], ELM-ART [7] and ACE [2].

ALE produces individualized courseware for the students depending on their current state of knowledge, their preferences and learning styles. The author specifies the metadata according to which such adaptation methods like additional explanation, prerequisite explanation, comparative explanation, explanation variants or sorting can be implemented, taking into account the user model. In this way, the system can adapt the sequence of learning objects according to the chosen learning strategy. For instance, a concrete example can precede or complement an abstract statement if the student needs it. To reduce the cognitive overload of the learners various annotation techniques are implemented. As a difference to earlier adaptive learning management systems ALE also integrates the possibilities of using methods of user modeling and data mining for building expertise networks and supporting human resources management in knowledge management for organizations. High quality expert finding and colearner finding algorithms can build on detailed user and learner models from ALE.

This paper describes latest extensions of the integrated authoring and learning, a main aspect is the integration with an information brokering platform broker's lounge to integrate highly dynamic contents into a curriculum and support learners after finishing an online curriculum with explorative tools.

---

[1] Web based intelligent design system (WINDS) [1] is EU funded project in the 5th framework of the IST programme # IST-1999-10253.

Reusable Learning Objects Structure

The WINDS authoring tool supports authors in building independent learning objects and structuring them in a default course hierarchy. Nevertheless the underlying knowledge representation and storage allows for reusing and handling learning objects independently and combining them in new dynamically generated courses later on. This assures that the system is able to produce individualized courseware for students depending on their current state of knowledge, their preferences and learning styles. With *course units, learning units, and learning elements* course authors can create an arbitrary structured hierarchy of learning objects which also represent the default learning path for the students. The course authors can also specify relations between learning objects based on a subset of the Dublin core recommendations [8]. These include prerequisite relations, *part_of*, and *related_to* relations between course units, learning units, and learning elements. All these learning objects can be associated with a subset of the Learning Object Metadata defined in the IEEE LOM specification [4]. Learning elements as the leafs of the course hierarchy are built of single content blocks. A content block can either be a text segment (ASCII, HTML, other), a URL, or a file that is uploaded to the server. Every *content block* has a pedagogical role what gives additional possibilities for reusing and even recompiling dynamic learning elements from content blocks of different pages.

Additionally all learning objects in a course unit will be linked dynamically by the underlying index defined by the course authors. The index reflects a common understanding of the domain and the subject matter. The index terms are described by a term name, a description, synonyms, and relations to other terms. When the author publishes a learning object or previews it in view with terms mode the system parses all materials in this learning objects and stores occurrences of index terms in the database. This allows giving the learner different approaches for working through the learning materials.

The types of learning objects in ALE as well as detailed descriptions can be found in [9], [10], [11].

Authoring highly dynamic content

Facing increasing information overload, the individual effort for receiving important information, qualifying on hot topics and applying knowledge successfully in daily life becomes more and more challenging. Analyzing the information supply chain a key issue can certainly be seen in collecting and creating e-learning content that is "up to date". In rapidly developing domains authors often are confronted with the problem of getting together all recent developments and it is even more complicated to update their content rapidly without any programming knowledge and major multimedia production efforts.

By the combination of ALE for creating standardized learning materials with an information brokering system "Broker's Lounge" [12] we now enable the authors of online learning materials to integrate static learning materials with highly dynamic information from information brokering tools that monitor specified information resources in the inter- or intranet. These resources are monitored based on an ontology of important domain concepts and categories that can be initialized from the course index and can be extended in a full sized information brokering tool. By this we ensure a semiautomatic reduction of information quantity while still giving the author the control over the information quality included in course materials.

Now each course has four main parts:

- The *Units* folder includes all the learning units and learning elements forming the structure and content of the course.
- The *Index* is at the beginning a universal department index prepared in advance and chosen by the author who can enhance it. Administrators can create master indices that can be imported into single courses. Furthermore the systems allows teachers to export their indices to a standardized XML format that enables the system to directly integrate external documents or application in which theses index terms are used as annotation tags.
- The *Documents* are supplementary sources of information relevant to the course. Specialised portals with up-to-date materials can be referenced here. The possibility to view external documents enables the system to include highly dynamic information into the courseware.
- The *Dynamic Learning Objects* give the authors the possibility to integrate highly dynamic learning materials into their courses. The DLOs take the index terms as a base ontology for the Broker's Lounge to configure web-robots spidering the documents specified in the documents section. The robots can be configured with a time schedule configuration and in a variety of ways. Beside monitoring websites they can be used to spider online databases and information resources with authentication need or document repositories. This allows authors to integrate a wide variety of learning communities and shared document repositories into courses.

The course index can also be used to view external documents and learning elements with index terms highlighted and hyperlinked to the term's explanation. Therefore by browsing from learning elements to index terms and then to external documents, back to index terms and so on, the students have individualized learning paths based on their interests. Nevertheless the system can keep track of all inspected index terms, learning objects, and external documents to follow the students learning process.

Personalized Learner Profiles and Skills Management

Professional profiles develop fast in certain domains like media industries or other sectors which are based on short product cycles and fast changing technology. Even in traditional sectors like architecture by the integration of new technologies new professional profiles develop what has an important impact on education in universities and training in industry. From our point of view this is reflected by a stronger focus on skill management systems and their integration into LMS.

In the Learner's Lounge project we combined a educational brokering system and a LMS to support profile and skill management on different levels:

1. Interest profile management: Interest profiles that can be developed to support professional development in the long term view and integrate all types of educational offers from classical class room training to online learning with ALE.
2. Competencies, skills, and knowledge management for professional profiles: Based on a detailed analysis in the WINDS project a methodology was developed to build the WINDS skill grid that allows for a detailed definition of competencies, skills, knowledge and a classification of all learning objects in the ALE environment according to the grid. Therefore based on the specifications of the interest profile and the professional competencies a learner wants to achieve a dynamic curriculum can be compiled by the ALE system.

Conclusions and Further Research

The ALE authoring platform supports reusability of the learning objects and as a new feature the integration of highly dynamic contents. The created learning objects can be delivered in a variety of ways, from classical web-based training to combinations of classroom events and online seminars, or even as personalized books. Beside the possibility for cross media publishing and the flexible combination of learning objects in individualized curricula the indexing system and the connection of the learning objects allows for personalized coaching of students. Currently the system is extend to allow the integration of real time content and support situated learning scenarios in field trips.

Social Justice

Abstract

The aim of this Intercultural and Cross-Cultural Teaching Portal is to establish communities of reflection and practice for diverse educators in P-12 educators who are teaching or preparing to teach in an educational environment. By coming together, we share our commitments and concerns as we review and recapture our experiences in facing challenges of educating everybody's children. We wanted to create spaces specifically where individuals of the same racial/cultural/ethnic backgrounds to communicate with and learn from each other. We also encourage intercultural and cross-cultural communications among teachers of different racial/cultural/ethnic groups. We raise questions such as how our cultures shape our vision of children's teaching and learning in general. More specifically, how our social and cultural identity helps to mold our interactions within the classroom.

The purpose of these forums is to facilitate discussions on multicultural education and social justice issues that may arise in classrooms and school communities. We realize that some groups feel more comfortable sharing with individuals whose worldviews are somewhat similar in nature. Although, we recognize that everyone bring a different set of values, attitudes and beliefs, we believe that some educators will feel more comfortable sharing in their own racial caucus group. Therefore, our position is that we develop racial/ethnic caucus groups so that, for example, Asian American educators who are teaching in intercultural and cross-cultural classroom environments can share their experiences as Asian and Asian Americans. We are interested in hearing from and engaging all educators nationally and internationally who are working in intercultural and cross-cultural school environments.

Our goal is to provide a forum where all educators are heard and their voices are liberated. We provide each forum where each group can share and express concerns within and across racial/ethnic and culture groups, as well as, a general forum for everyone. While anyone can enter any forum, we hold a position that each group be allowed to share comfortably based on their worldviews.

Higher Education's Challenge for Academic Excellence in the 21st Century: Can Old Profs Be Taught New Tricks?

Renee Wallace, PhD
Associate Professor
Department of Secondary Education and Foundations
Florida A&M University
United States
renee.wallace@famu.edu

Abstract: Teaching tenured faculty (old Profs) to integrate e-learning methodologies to enhance student learning and instruction in higher education is a formidable task. But, the task is not impossible. In 1997 Florida A&M University received national recognition when it was named the 1997 Time Magazine/Princeton Review College of the Year. Due to the institution's many recognitions, Florida A&M University has experienced more than a twofold growth in student enrollment over the past several years. This rapid growth has taxed both facilities and the ability of the faculty to deliver quality programs of instruction. Faculty began to inquire and look for opportunities and applications for creating e-learning opportunities. Pearson Education provided a vehicle to help us to begin to create an e-learning environment in the Colleges of Education and Arts and Science to enhance the tenured professors (old Profs) capabilities. Course Compass, BlackBoard, and WebCT have become three of the online technology vehicles for the delivery of instruction and creation of e-learning opportunities in both the College of Education and the College of Arts and Science. The e-learning environment has provided online technology coupled with many visual learning tools, and authorware tools that were not available in the traditional learning setting. The wave of enthusiasm has crossed over to other disciplines. Technically savvy faculty are requested to share the e-learning (new tricks) pedagogy with there tenured professors (old profs).

Computer technology, like any other educational tool, can be used to further educational productivity in several ways. It can help professors do a better job of introducing and reviewing basic information, thus increasing the efficiency of traditional instruction, and indeed, many efforts, both publicly and privately supported, now pursue this goal.

Some of the most fruitful applications of computer technology derive from its capacity to present educationally powerful, dynamic visual images. Having several representations available allows a better match between students and the subject matter. Thoughtfully designed computer software can present multiple dynamically linked representations in ways that are impossible with static, inert media such as books and chalkboards.

For many faculty , acquiring the knowledge and skills necessary to teach for understanding involves a subtle but important shift in beliefs. Reinforced by the structure and culture of their departments and institution, many tenured faculty believe their role is to transmit knowledge, as formulated and presented in textbooks. To engage students in a process that includes forming, testing, and critiquing hypotheses, faculty must accept the value of a more flexible set of professor and student roles, and adopt a broader view of knowledge, teaching, and learning. One central aim, therefore, must be to identify the materials, resources, and supports that will help tenured faculty to make these adjustments and use the online environment effectively.

The e-learning environment as a new mode of learning promises to transform the experience of the classroom in a number of fundamental ways: by augmenting traditional textbook materials with online resources and content portals; by enhancing customary "chalk and talk" lectures through the use of rich multimedia and interactive content; and by extending student discussions beyond the walls of the classroom via a wide range of new communications platforms supporting inter classroom collaboration.

According to McKinsey & Co., a New York management-consulting firm, almost half the teachers in the United States lack adequate computer training. Given this lack of technical savvy, it is not surprising that although many teachers use computers personally, only 20 per cent use them regularly as an integral part of their classroom instruction (Bulkeley, 1997). Larry Cuban (2000) offers the following insights on the real underlying issues in a recent article in *Education Week*. Cuban is convinced that teachers are not taking

BEST COPY AVAILABLE

advantage of new tools to the extent that they could for several reasons: contradictory advice from experts; intractable work conditions; demands from others; the inherent unreliability of new tools; and policymakers' disrespect for teachers' opinions (see Bulkeley).

Despite the availability of graphical, "point and click" software tools, the process of creating and posting web pages on the Internet remains an intimidating prospect for many faculty. According to the research firm IDC, less than 1 percent of the U.S. population has taken a course online. Yet, online learning has appeal for traditional as well as non-traditional students, and university faculty members are increasingly expected to integrate technology use (including use of the Internet) into their instruction. Rather than teaching in a purely online format, many of these teachers are creating "hybrid" courses that include some online content and activities within a traditional class format.

Ironically, while colleges and universities are striving to be on the cutting edge of technological advancement in hardware, the lecture remains the dominant pedagogical method. This method of learning uses the professor (old dogs) as a "sage on the stage," a font of knowledge from which students drink passively. Learning is then judged in terms of the students' ability to regurgitate the knowledge that they have consumed. Unfortunately, many faculty (old dogs) today still cling to this traditional pedagogical model.

One can often hear from tenured faculty (old dogs), “I do not know how to use a computer”, “I have been teaching for 20 years, I did not need a computer then and I do not need one now”. “I do not see what I can use a computer for”, “I have students that know more about computers than I do”, “I cannot type”, and./or “I feel totally inadequate when it comes to utilizing the computer.” *Techfear* is rampant among faculty (old dogs) . The fear of using a computer, the fear of not knowing what to do with it, and the fear of being left behind in this technological age are very real. There are so many applications, so many hardware choices, and in general, so many uses that this fear is overwhelming many of our colleagues. The first thing we have to do is alleviate the fear. Our goal was to help tenured faculty (old profs) integrate a new technology into their curriculum and accustomed teaching style (new tricks).

At colleges and universities the use of the Internet and Web for learning and teaching is causing a major change in the landscape of education. Building upon decades of computer networking activities (e.g. e-mail and bulletin board systems), the Internet has produced phenomenal growth in the extent and scope of online education. For some faculty at Florida A&M University online education has created a new paradigm for teaching and learning different from the traditional classroom experience.

We have found that online courses can also allow students who might not participate in a traditional class discussion to engage both their professor and fellow students in dialog. Asynchronous online discussions (in which students participate on their own time, not necessarily in real-time with each other) can permit more thoughtful responses from students because immediate replies are not required. Textbooks and other resources can be consulted and cited in posted responses. Every student can potentially be asked to respond to a question posed by the professor, via discussion group or e-mail. These outcomes are difficult to achieve in a traditional classroom setting, but realistic for an online course, once materials and activities are available on the Internet. For that task, online courseware e.g., Black Board, WebCT, CourseCompass, ect. can be invaluable.

Course content can be entered either online in the web browser or uploaded (like Word documents saved as HTML/web pages). Course announcements can be posted, a class calendar created, discussion forums and chat rooms created, as well as "digital drop boxes" for submission of student assignments. Students can be added and assigned to groups for project purposes, and can post work on group web pages as well as correspond with the professor and classmates. Assignments can be posted, grades assigned for students to view after logging in, and a "virtual classroom" created allowing for real-time interactions between instructor and students. These interactions are not limited to text chat, but can also include use of an electronic whiteboard.

The distinguishing advantage of online courseware, according to many FAMU faculty who have used it, is its ease of use (new tricks). Setting up the course options does not require programming or coding of any type. Files do not have to be "uploaded" to a web server using another program: everything is done by typing, pointing, and clicking within the web browser. Internet users with a modest amount of computer experience can utilize Blackboard, Course Compass or WebCt to start creating their own online course materials in a comparatively short time, compared with that required to post and upload web pages created with tools such as Frontpage or Dreamweaver.

But the most important overall impact of online courses is the emphasis they place on critical thinking and discourse. The one thing that happens in all online courses, regardless of the discipline, is that students communicate a lot more with each other and with the professor. They discuss ideas, analyze, evaluate, argue, debate, and question.

While no one can predict the future with absolute certainty, it does appear that online learning will continue to grow in popularity in the years ahead. Many companies and investors are literally banking on this trend. Eduventures.com Inc. predicts the higher education e-learning market alone (not including K-12 education) will grow from $4 billion to $11 billion by 2003.

Thankfully, online courseware services like those described here is helping to make the transition to a web-based or hybrid course (new tricks) a much less painful experience for faculty (old dogs). For many, the process will prove to be not only challenging and rewarding, but also a lot of fun, (new tricks) as students are provided with new educational opportunities thanks to the proper use of technology tools in the hands of skilled faculty (old dogs)..

The work accomplished so far suggests that the answer to Higher Education's Challenge for Academic Excellence in the 21st Century: Can Old Profs Be Taught New Tricks? Is a resounding yes, e-learning can play a substantive role in developing a new breed of old profs with new tricks for the 21st century.

Video Festivals

A demonstration of exemplary pedagogies designed for low-budget producers and low-tech learners

Lisa Holstrom, Ed.D.
University College
University of Cincinnati
Cincinnati, OH USA
Lisa.Holstrom@uc.edu

Abstract: Many producers of video do not have the resources to replicate the high-production value of many commercial videos, but prefer the visual delivery of content over a text-based course. This presentation demonstrates how video can capture various pedagogies and instructional methods and incorporate them into a complete e-learning environment. Designed for low-budget producers, this high-quality, engaging, and interactive combination of Blackboard and video is perfect for low-tech learners.

Pre-recorded, one-way video has been used for educational purposes for over half a century, and its lack of interactivity has bothered instructors for almost that long. The infamous "talking head" was often accompanied by a series of worksheets and assignments that afforded students little timely feedback from an instructor and no interaction with other learners. For students who needed education but lacked university access, this inadequate system was the only recourse.

With the advent of the Internet, instructors have embraced the interactivity component of email, discussion boards, and chat rooms. Streaming video, often two-way, has allowed instructors to put a face on their teaching and provides students with immediate feedback while providing instructors with the non-verbal cues that are absent in text -based e-learning.

Unfortunately, a gap exists between the technology skills and capabilities of many learners and the skills and computer capabilities needed to be successful in this highly interactive Internet environment. Streaming video is only effective over fast equipment and lines with high bandwidth. Although innovations may facilitate the delivery of this multi-modal distance education in the future, there's a population of low-tech learners that need accessible education now.

Which brings us back to the strategy of using low-tech, pre-recorded video with Internet interaction as a vital component of the instruction. Educators recognize the advantages of video: It pulls learners together around a visual prompt (Stigler 2002; Finn 2002); because video utilizes more senses, learners retain more knowledge (Osciak & Milheim 2001; Lewis 1997); and adults enjoy learning in an environment that appeals to multiple intelligences (Brougher 1997). The Internet action wraps around the video because educators realize the old paper-and-pencil exercises are insufficient. "Unless the videos are followed by discussion and practice, they turn into a 'one-shot deal' and lose their effectiveness" (Lauro 1995, p. 65). The Internet has become the vehicle through which discussions are facilitated; particularly for distance learning, these ediscussions can promote a sense of community that is often a void in the elearner's experience.

In these truly multi-media, multi-modal learning environments for low-tech learners, video takes center stage. This presentation addresses the challenges of producing low-budget video that surpass the appeal and interest of the "talking head" while maintaining the pedagogical integrity of effective classroom instruction.

Developed for the Early Childhood Learning Community at the University of Cincinnati, over 500 hours of live-to-tape video comprise a complete Associate's degree. Faculty was told to dream of the ideal classroom instruction. What would it look like? What would it sound like? After careful planning, each instructor was videotaped modeling their effective pedagogical approach to video learning. As administrators, we have found the results to be fascinating and enlightening. Students have found the lectures concise, relevant, interesting, and thought-provoking.

This presentation will showcase the various pedagogies that faculty chose to implement in their lecture series. From incorporating commercial video (with appropriate permissions) similar to "Masterpiece Theatre," to a set and discussion that replicates the familiarity in the popular women's show "The View," faculty deliberated and collaborated until they arrived at a pedagogy that fit their topic. They captured on film a once-in-a-lifetime presentation of theory and practice applications.

For example, the faculty member taping the Math and Science in Early Childhood Education demonstrated many activities and manipulatives that would have been inconvenient and expensive to repeat every quarter in the traditional classroom. The English instructors, who were initially adamant that teaching composition through video was pedagogically impossible, did a light-hearted dyad discussion around the various common problems they see in students' writing and addressed these issues with both forethought and humor. Guest speakers who would certainly be unavailable every quarter for "repeat performances" were utilized and their expertise was captured on tape.

These examples and more will be viewed because this type of pedagogical creativity is crucial to the production of low-cost video for low-tech learners. The presenter will subsequently lead a discussion around the various pedagogies employed, the planning and logistics that went into each type of video presentation, and the corresponding Internet interactivity that makes this program unique. Student quotes will be offered to attest to the effectiveness of this approach to e-learning. Of particular interest to many participants will be the manner in which this program has been deployed to appeal to low-tech learners. Furthermore, the video showcased here can be replicated without a large investment in production equipment or time.

Virtual Field Experiences for Pre-Service Teachers

Patty LeBlanc, Ph.D.
Department of Education, Stetson University USA
pleblanc@stetson.edu

Elizabeth Heins, Ph.D.
Department of Education, Stetson University USA
eheins@stetson.edu

Abstract: This video is one in a series of teacher training modules based on real-time teaching in a 3rd and 4th grade classroom, beginning on the first day of school. Video data were captured during two-way interactive videoconferencing sessions between Stetson University, Bethune-Cookman College, and Bonner Elementary. Pre-service teachers at both institutions observed the target classroom on a regular basis using videoconferencing technologies and a variety of observation forms. Student and faculty reactions and insights were captured on video to augment written comments. The videotapes were then edited to create modules for undergraduate and graduate teacher education. A handout will be disseminated directing participants to the T3 website, where they will find information on videoconferencing, the data collection process, classroom observation forms, descriptions of the teacher training modules, and other resources available to educators.

In June 2000, the Department of Education at Stetson University received a grant awarded by the U.S. Department of Education to support the integration of technology into pre-service teacher education. Located in central Florida, the T3 project is a consortia of five key partners: Stetson University, Bethune-Cookman College (an historically black college), Volusia County Public Schools, the Florida Independent College Fund, and Time Warner Communications. The purpose of the T3 project is to prepare pre-service teachers to effectively infuse technology across the curriculum to enhance teaching, learning, and student achievement.

Using T3 grant funds, two-way interactive videoconferencing capabilities were established at Bonner Elementary to enable pre-service teachers at Bethune-Cookman College and Stetson to "peer into" an elementary classroom in order to unobtrusively observe real-time teaching. Bonner Elementary is an inner city school located in Daytona Beach, Florida. The teacher, Ms. Carol Colucci, participated in a summer technology boot camp at Stetson and subsequently volunteered, along with her 3rd and 4th grade students, to be the videoconferencing test case for virtual field experiences with our pre-service students. The trials and tribulations of videoconferencing are discussed in previous presentations (see http://www.stetson.edu/t3/resources.htm).

Typically, teacher education faculty at Stetson and B-CC schedule virtual field experiences at specific times to view a specific lesson in a specific content area. In this way, faculty can direct the students' attention to a particular strategy, skill, or learning construct as the focal point of discussion about the observation. Pre-service students were thus exposed to a commonality of experience that cannot be replicated in other types of real-time classroom observations. In addition, faculty and students could observe Ms. Colucci and her students at any time during the school day in the professional development centers at both campuses. Some faculty required students to make a certain number of virtual observations in their courses using classroom observation forms [see http://www.stetson.edu/t3/resources.htm]. Pre-service teachers were also encouraged to ask Ms. Colucci questions through videoconferencing before or after a lesson or by email if the question would interrupt student learning time. We are confident that what our students saw during the virtual field experiences was the regular stuff of everyday classroom teaching.

In addition to real-time videoconferencing, SVHS video data were gathered in Ms. Colucci's class, beginning on the first day of school. These data were subsequently compiled, edited, and used as the basis for pre-service teacher training modules and for graduate education. The video to be shared in this presentation will consist of real-time teaching and pre-service teachers' observations about the lessons. A handout will be disseminated directing participants to the T3 website, where they will find information on videoconferencing, the data collection process, classroom observation forms, descriptions of the teacher training modules, and other resources available to educators.

Acknowledgements

The T3 project is funded by the U.S. Department of Education as part of Preparing Tomorrow's Teachers to Use Technology Initiative (PT3). The project will receive $967,263 over three years, which is 42% of the total cost of the project. The T3 consortium will contribute $1,343,060 (58%) of the total project costs over three years.

An Online Digital Video Library to Use as a Knowledge Base for Teacher Education

Problem

Geoghegan (1994) reported that despite U.S. expenditures of $20 billion on instructional technology in higher education between 1970 and 1994, no more than 5% of faculty use technology other than a substitute for the blackboard or overhead projector. In addition, he estimated a 15% saturation level in the diffusion of technology among higher education faculty. Many plausible explanations for this lack of infusion (Massy & Zemsky, 1995; Shields, 1995) exist; however, an intervention exists to help address the problem—appropriate modeling.

The Need for Modeling

Teacher education students and teachers need to see many examples of standards-based instruction to overcome their "apprenticeship of [miseducative] observation" (Lortie, 1975), and there is considerable agreement about the need for modeling in both preservice and inservice teacher education (Ball, 1990, 1997; Rahal & Melvin, 1998; Schuman & Relihan, 1990). Observing teachers in the class is one way to see models, but there are limitations to this approach. The primary limitation is the logistical infeasibility of having the time to visit other classrooms and seeing a variety of quality lessons.

Solution

The use of a digital video library (DVL) containing electronic models of exemplary teachers and supporting resources provides an easily accessible online resource anytime, anywhere. A DVL is much more than a technologically advanced counterpart to physical libraries. The DVL is just one example of the broader category of digital library (DL). Digital collections often include traditional written materials but can also encompass resources as varied as animations, music, and video clips and can provide significant opportunities for user interaction.

DVL and Pedagogy

Implementing the DVL in teacher education learning environments provides substantive learning opportunities and models technology infusion. The DVL provides a shared experience (or "anchor") for teacher educators and preservice teachers to discuss and analyze with a partner and/or group in a unique combination of learning tools. Using the DVL, teacher education students and instructors move easily from a video clip of classroom instruction to a list of software tutorials to a lesson activity designed to employ curriculum and national technology standards. They are able to observe classroom instruction without leaving their own classroom or homes, and they are able to compare conclusions and reactions to the video clip. Teacher education faculty benefit from use of a DVL. Scheduling demands can often make faculty development and independent learning difficult to accomplish. A DVL provides anytime, anywhere instruction for teachers who want to learn more about new technology tools and promising practices in technology infusion.

Community. A DVL can help to foster a sense of community between users, even if those users are separated by distance and time. A commentary engine allows users to contribute to the resources of the DVL and learn how other users have responded to the information. Shared experiences allow DVL users to have something in common when discussing technology infusion issues. The DVL allows a group of instructors, students, or administrators to access and evaluate the same information and examples.

Interaction. The DVL is a highly customizable tool, and developers can give users a high quality experience. DVLs offer a variety of searching operations, refined navigational methods, and intuitive interfaces. A DVL gives the user a higher degree of interaction with the materials than a traditional library or a simple Web page can.

Materials Management. The organization and hierarchies of a DVL offer a solution to problems with materials management and archiving. Resources (e.g. expert commentary) are linked and digitally stored in a DVL, using metadata. A DVL not only offers an efficient system for managing resources but it can make them more valuable. Learning objects are exponentially more useful when they are identified, described, collected, distributed, and shared.

DVL Presentation

This session will present digital video lessons of PK-12 teachers modeling the National Educational Technology Standards (NETS) for Students and teacher education faculty modeling the NETS for Teachers. Presenters will (a) briefly describe the video production cycle, (b) provide a brief overview of the design and development methodologies, (c) discuss DVL innovations, (d) present four examples of the available online digital video lessons and (d) propose the DVL as an instantiation of Hiebert, Gallimore and Stigler's (2002) call for a teacher education knowledge base.

Creating a computerized multimedia Chinese language lesson from authentic web text, using the KEY 4.0 software (for both PC and Mac)

1. Description of the KEY 4.0 software

The new (2002) KEY 4.0 program from the Ottawa-based developer cjkware.com inc. is a software system for writing, learning and teaching Chinese (Japanese and Korean word processor included). KEY 4.0 is available for the PC (all Windows versions) and as "MacKEY 4.0" for the Macintosh (OS 9 and OS X). Originally a word processor for Chinese, this new version includes several innovative authoring, teaching and learning features for the Chinese language.

For example, when Chinese character text from an outside source - such as the Internet - is copied & pasted into the KEY edit screen, the boundaries of the Chinese words are automatically reconstructed, thus laying the basis for analysis and comprehension of the Chinese text through the built-in

- Chinese/English dictionary (with Tool Tip lookup),
- "Pinyin With Hanzi" feature (automatically providing a second line of Pinyin with tone marks for the Chinese character text),
- Text To Speech,
- Automatic glossary-building,
- The Timed Reading Module that automatically creates multimedia lessons, and
- The ability to create hidden annotations, even for multi-part grammatical structures, that can be viewed through the Annotation Tool Tip.

2. Objectives of the session

The session is intended to introduce the most recent computer- and internet-based instructional strategies for the Chinese language, taking advantage of the newly (2002) added multimedia authoring, teaching and learning functions of the KEY Chinese software. The objective is to demonstrate certain interactive software-based algorithms that

- Enable learners of Chinese to analyze and comprehend authentic Chinese text in electronic format, such as from the Chinese web,
- Enable teachers of Chinese to automatically generate a dynamic multimedia lesson from static Chinese text in electronic format, such as from the Chinese web,
- Represent a tool for automatically converting any foreign-language Internet text into a foreign-language teaching/learning format.

In the contexts of FLA (Foreign Language Acquisition) and SLA (Second Language Acquisition), the session shows a way to complement classroom-based instruction with a human teacher and print-based teaching material with supplementary software-based teaching- and learning techniques.

3. The intended audience of the session, and prerequisites

The session will be of interest to anyone who deals with electronic text, such as Internet text, that is written in a foreign language, either for comprehension of the contents, or for learning the foreign language. In particular, it will be of interest to language learners and teachers, because it illustrates the principle of automatically converting static text into a dynamic multimedia lesson. Although the demonstration uses examples from the Chinese web, it is not necessary for the audience to know Chinese. On the contrary, in order to show the efficiency of analytic computer-based comprehension, learning and teaching tools like KEY, the session gets its point across even better to those members of the audience who do not know Chinese. During the interactive session, the participants will have the opportunity to use the software tool to analyze a randomly chosen text passage from the Chinese web, and run the passage as a learning lesson.

4. Overview of the interactive session

To reflect the real-world computer learning environments, the software will be demonstrated on two different operating platforms: KEY 4.0 on a PC with Windows 2000/XP, and MacKEY 4.0 on a Macintosh computer with OS 9 and OS X. The session centers on the KEY 4.0 features for analyzing and processing Chinese text from outside sources (email, Internet, other Chinese software etc.), and creating interactive multimedia lessons using authentic Chinese text, through the Timed Reading module. Assuming that a learner / teacher of Chinese wants to capture and analyze text from a Chinese web page, and also use it as learning / teaching material, these features are demonstrated by first randomly selecting a Chinese text on the Internet. We start by copying & pasting the Chinese character text from the web into the KEY edit screen; in detail, we

a) Select (=highlight) the Chinese web text displayed in our browser, and "copy" it on the clipboard;
b) "Paste" the text into the KEY screen;

c) Select (=highlight) the text, and from the KEY Format menu choose "Hanzi with Pinyin". This displays a second line with the Pinyin-with-tone-marks equivalent of the Chinese character text. We can see from the word segmentation of the Pinyin transcription that the word boundaries were automatically reconstructed when the text was copied & pasted into KEY;

d) Use "Text To Speech" to listen to highlighted passages;

e) Use the "Dictionary tool tip" to display the meaning(s) of the Chinese words and their Pinyin pronunciation;

f) Check "Read tool tip with Text To Speech" (on the KEY View menu) to hear the Mandarin Chinese reading of the words;

g) Convert the Chinese text into a dynamic, interactive multimedia lesson, by press the "TR" (Timed Reading) button on the KEY toolbar, and specifying the various "checks" we want to include in the lesson;

h) Run the multimedia lesson in an interactive mode;

i) Use the Annotation feature to annotate certain words, grammatical particles, multi-part structures etc.; hide the annotations, and retrieve them with the "annotation tool tip".

j) Automatically build a Chinese/English glossary for our Chinese text, by:
   - Copying/pasting the text beneath itself, so we have it on the screen twice;
   - Using "Return" to segment the second copy of the text into words, one at the beginning of each line;
   - Clicking "Convert To Glossary" (Format menu), which automatically provides the pronunciation and the English meaning for each term, arranged in columns.

Detailed demonstration of the interactive learning features of KEY 4.0

The session concentrates on the two most recent enhancements to the KEY software package: the "Timed Reading" module and the "Annotation" feature. These features constitute a CALL (Computer Assisted Language Learning) tool for improving Chinese language reading and comprehension skills. By segmenting a Chinese text passage, such as text from the Internet or teacher-generated KEY text files, into manageable syntactic units, the Timed Reading module allows the reader of Chinese to practice word segmentation, phrase comprehension, eye movement, and thus enhances overall reading efficiency.

For learners and teachers of Chinese: Automatic authoring of multimedia lessons with the TR button on the KEY 4.0 toolbar:

- Write, or copy/paste the text you want for reading practice (from a Chinese website, or other electronic source). Press the TR button on the KEY toolbar, which automatically segments the text into manageable portions and takes you directly to the Reading Timer panel, where you can set the various options (like Pinyin, Tones, Sound etc.). Clicking on "Start" will begin the automatic reading cycle. Choose this fast way to time-read a Chinese text if you want to accept the default segmenting of the system.
- If you wish to manually segment the text, do not press the TR button, but click on "Select Timed passage" on the KEY "Edit" menu. Enter your preferred segment length and click OK to view the segmented text, and make changes in the segmentation if necessary. With the segmented Chinese text on a yellow background displayed on the KEY screen, click on the item "Reading Timer" (on the KEY "View" menu). This brings up the Reading Timer panel on which the display time per Hanzi can be set (scale from 100 ms - 3 sec per Hanzi), together with other Timed Reading parameters.
- Notes on the Reading Timer panel:
  a) The punctuation delay applies to comma, semicolon, full stop, question mark and exclamation mark; it does not apply to the Chinese serial comma "dunhao".
  b) If "Display Word Boundaries" is checked, a GREEN half space is inserted between the Chinese words, to assist the reader in recognizing the word boundaries in the text.
  c) A Read-aloud practice mode can be set by checking "Sound check": in this mode, another phase is added to the Timed Reading of each segment, during which the reader hears the segment read out aloud by the TTS module of KEY.
  d) With "Pinyin check" enabled, another practice phase is added to the Timed Reading of each segment, during which the reader sees the Pinyin-with-tone-marks version of the segment displayed in a second line above the Hanzi text.
  e) With both "Sound check" and "Pinyin check" enabled, the loud model reading through KEY and the Pinyin-with-tone-marks transcription of the segment go hand in hand, in the additional phase.
  f) Checking "Enable Tool Tip" activates the Chinese/English tool tip dictionary. This allows the reader to query the English meaningof a Chinese word by moving the mouse pointer onto the word (DO NOT CLICK, just hover). While the tool tip window with the English meaning is displayed, the timer is temporarily halted.
  g) If you have made annotations to the text, you may want to enable "Annotation Tool Tip", which will display the annotations when pointing at the annotated word.

In summary, enabling all features in the checkboxes of the Reading Timer panel allows the learner to thoroughly analyze a Chinese text passage, within the self-imposed time constraints of the Reading Timer. Thus, the Timed Reading module of KEY is an interactive learning tool for reading and comprehending Chinese text, by teaching word boundaries, pronunciation, Pinyin-with-tone-marks transcription and the English meaning in a dynamic and integrated multimedia lesson.

Abstract: The University of Idaho has been engaged in promoting the development of web-enhanced and web-based courses through a multi-stage effort to promote the integration of technology is higher education. This project specifically focuses on providing faculty development, technology enhanced facilities, and individualized assistance to higher education faculty as a means of integrating technology in higher education courses. Using technology enhanced facilities, faculty training is provided on classroom equipment, personal technology and software, and instructional design using an online learning system developed at the University of Idaho.

This poster session will provide information regarding faculty training workshops and individualized assistance, facilities improvements, and a demonstration of the integrated online learning system in use at the University of Idaho. Information regarding the evaluation and impact of this program will also be made available.

Introduction

It is becoming commonly understood that one challenges facing technology integration in higher education, specifically web-based technology, is a lack of training and development time (Bonk, p. 10). Further, many higher education faculty do not feel comfortable using online course systems and tools (Bonk, p. 6). When planning the PT3 program at the University of Idaho, the College of Education faculty and staff developed a strategy to address this problem and further impact the integration of technology into courses taken by pre-service teachers.

Beginning in 1999, the PT3@UI program at the University of Idaho was funded by the US Department of Education to promote the integration of technology in the pre-service education program. The PT3@UI program was to include continual faculty training, facilities improvements to develop several technology enhanced classrooms, and specific training on an online learning system developed at the University of Idaho.

Description of the PT3 program

Faculty training for the PT3 program has centered around providing basic and advanced training to faculty members on various software programs and training on the equipment now available in the technology enhanced classrooms. In year 1 of the program, faculty self-selected either basic or advanced training in productivity software and web development software. Year 2 of the program continued these efforts by providing additional training on the development of web-based materials to those ho had attended the basic skills development in the previous year. Faculty members who attended the workshops were provided with a stipend and copies of the software that was used.

Facilities improvements have been ongoing throughout the PT3 program. In six classrooms in the College of Education and other buildings on campus, SmartBoards, projection units, and computer systems were installed. These classrooms were designated as teaching classrooms rather than computer labs to promote their use in teaching of course rather than simply as student computer labs.

One of the overarching goals of the PT3 project was to promote the development and use of web-based technology as an enhancement to traditional on-campus courses. As faculty developed their technology proficiency, they were further trained on instructional design for web-enhanced courses and the integrated online learning system developed at the College of Education. In addition to providing valuable web-based tools for courses, the use of the online learning system into the PT3 program also provided an opportunity to involve faculty in the further improvement of the online learning system. The result of this collaborative effort was a significantly improved online learning system designed with specific faculty needs in mind. This learning system is now in its second major release at the College of Education and is also being used in other institutions and programs around the United States.

The work of the PT3 program represents the level of institutional involvement that can have a significant impact on the integration of web technology into higher education courses and also is representative of an efficient, effective, and relatively low-cost program that can support faculty development and web technology development at an institution of higher education.

Description of Poster Session

The PT3 program at the University of Idaho is a unique program that has promoted the integration of web-based technology by directly addressing faculty needs. This poster session will largely focus on the lessons learned during this program and the efforts that positively and negatively impact the further integration of web-based technologies. The intent of this poster session is to share information and experience with others involved in similar endeavors and to further disseminate the experience and expertise gained by the program.

Using Discovery-Based Online Learning in the Teaching of Computing

Dr. Ken Abernethy and Dr. Tom Allen
Department of Computer Science
Furman University
United States
ken.abernethy@furman.edu, tom.allen@furman.edu

Abstract: This paper reports on the creation of a set of interactive Web-deployed discovery-based learning modules to enhance student learning in an introductory computing course for non-computing majors. The modules created apply a discovery-based methodology in a way that transfers exploratory activities to asynchronous pre-class activities (delivered via the Web).

Introduction

Our introductory computing course is intended for students not planning to major in computer science. In such as course, it is important to integrate a sound conceptual understanding of topics along with practical, hands-on experience of using computing applications [Abernethy and Allen (1999)]. Merely training students to use specific software applications is to transfer a skill with an extremely short shelf life. It is more important to understand why things work the way they do, and we believe students should be exposed to a variety of seminal ideas from the enterprise of computing. Research in cognitive psychology has demonstrated that a command of facts is important, but that the expert has an understanding that supercedes a mere recall of facts. Experts differ from novices in at least three important aspects. First, experts have mastered a greater amount of content knowledge or technical detail about their subjects. Secondly, experts have an understanding of the relationships of important concepts rather than just isolated facts. In short, they know what is important and how things are related. Finally, experts can apply their knowledge to new instances in order to solve problems.

Incorporating Discovery-Based Learning

While we cannot expect to convert our students into instant experts, we might expect to improve their understanding of difficult subjects by modeling the processes by which expertise is accumulated. The goal of discovery-based learning is to introduce a subject by activities in which the student constructs an understanding of the subject based on these activities. Research on discovery-based learning suggests that students learn better and retain more with this approach [Duschl, (1990), Osburn and Freyberg (1985), and National Science Foundation (1996)]. Discovery-based learning involves a three-phase learning cycle: exploration, invention, and expansion. The exploratory phase provides an introduction to the topic that incorporates both an exposition along with activities that will model the later "invention" phase. In our case, these are delivered asynchronously via Web. The second phase is an organized in-lab team-based activity whereby students must apply what they have learned in the exploratory phase to new and different instances. The role of the instructor is that of facilitator. The expansion phase is incorporated in the lecture classroom where concepts are reviewed and related. In addition, the students are expressly asked to summarize key ideas learned.

Some Example Discovery-Based Learning Modules

What we present are the results of several iterations of our modified version of discovery-based learning as applied to learning about computing concepts. First of all, we have chosen topics that would benefit from a more technical development. For example, students can appreciate better how the Internet disseminates information if they understand more about the problems of transferring data from one point to another. Similarly, it is easier to comprehend the limitations of numeric representations on computers, if one understands the design choices for encoding numbers as data. Following are selected examples of the modules we developed. Clearly it isn't possible to portray the interactive nature of these modules in a static paper, so the reader is encouraged to consult the associated Web site http://s9000.furman.edu/nsf-ccli/entry.html to see these and other modules in their interactive online format.

Doing the Math: Computers and Binary Numbers

In this module, students are introduced to the design factors involved in representing integer values on computers. In the activities of this module, students are asked to explore the creation and use of positional and nonpositional number systems, the processes of encoding numbers in the binary system, converting between binary and decimal representations, and representing and manipulating signed numbers.

How the Internet is Organized

In this module, students are introduced to some of the details on how the Internet is organized as a store-and-forward packet switching network. They examine why store-and-forward switching is more efficient than other methods; the problems of identifying end-systems; and, how Internet routing works.

Exploring Technology for E-Commerce

In this extensive series of learning units, students are introduced to the basic technologies underlying electronic commerce. Each learning unit is partitioned into five learning modules each of which consists of a number of lessons containing interactive expository material as well as hands-on invention activities.

Assessing the Results

How effective were the integrated learning styles for students in introductory computing? On the whole students reported that they believed the learning modules were "more interesting" and made learning "easier." However, while subjective assessments carry some significance, they are usually not reliable measures of achievement. For this reason, a comparative study of two sections of the same course was used as a basis for assessing whether the discovery-based learning modules had any real impact on student learning. The evidence collected does support the hypothesis that students exposed to integrated teaching methods employing discovery-based learning do acquire a deeper and richer understanding of the material compared to those who learn by the traditional method of readings and lectures.

TITLE: Cost Effective Real-Time Video Conferencing for Instructionand Collaborative Learning in Music and the Performing Arts Via Next Generation Internet powered virtual laboratory environment

Bringing together master artists and performers either individually or in a group, to assist developing artists or performers either individually or in a group in a cost effective way poses a significant problem. Considerable barriers exist some of which are: the number of performers, cost of travel, rigid schedules, time required and availability of suitable sites. Use of the Internet2Next Generation Internet (NGI) test-bed Abilene and state-of-the-art but affordably priced video streaming gear and TV production and sound equipment have been piloted so as to deliver the teaching, training, and monitoring in a virtual classroom to develop minority musicians by master performers of a symphony orchestra.

This paper will describe the significant problem of providing training and exposure to a representative number of African-Americans and other minority musicians that can facilitate their professional aspirations toward membership in a symphony orchestra. This paper will describe the principal collaboratants to the pilot project, i.e., Florida A and M University, a historically black public university also a connector to the Internet1 Abilene Project, The New World Symphony Orchestra also an Internet2 affiliate and Star Valley Solutions, Inc. also an Internet2 corporate members. .

The goals and objectives of the pilot will be presented and a detailed look will be taken at the problems that need to be solved to realize these goals and objectives. The virtual classroom and performance center established in the pilot served as a teaching and learning environment for two organizations five hundred miles apart. The New World symphony selected professional artists consisting of five members was located in Miami, Florida and the one hundred ten members of the Florida A&M University Symphony Band was situated in their campus practice hall in Tallahassee, Florida. The critical issue of the bandwidth to support high-speed video streaming between the sites was addressed via a OC3 connection to the Abilene network from the FAMU campus and a DS3 connection from the New World Symphony.

Using kodecs furnished by Star Valley Solutions, Inc. the technical staffs of the New World Symphony and Florida A&M University sought to establish a video streaming rate that provided high quality video and high fidelity audio. This presentation will reveal to readers and attendees the lessons learned in selection and acquisition of digital television production equipment that is affordable and of high quality which can be packaged into a light-weight, portable television production system. It will also discuss the required testing; and configuration for optimum video streaming quality and the conservative use of bandwidth so that the e-learning delivery system can be established within circuits and wide area network connections that is much more prevalent and affordable for the high speed application than the NGI environment used in the pilot project thereby ensuring that this e-learning approach can be more easily replicated. The results of a survey of the New World Symphony performing musicians and the students and faculty of the Florida A&M Symphony band will be provided. The survey results will be analyzed to ascertain important questions of effectiveness of the e-learning laboratory and satisfaction with the virtual classroom environment established in the pilot project. Finally video excerpts of the live virtual laboratory application for E-learning will be shared with participants at the presentation..

Is the Integration of CALL into Language Curriculum affected by the environments surrounding it?

Ibrahim Suliman Ahmed.
Faculty of Medicine-International .I.University-Malaysia
Ibhims20002@yahoo.com

Technology affects our live in various ways (Ahmed, 2001:321). As language teachers, our goals are to encourage our students to participate in language talking and communicate with each other as well as with the native speakers (Ahmed: 2002). During this era we need to use the technology in our class for their advantages, but the environments surrounding us play an important role in using CALL effectively. Therefore are any factors that may assist us in our implementation of Computer assisted Language Learning into class such as students attitudes? And in the contrary are there any factors that may prohibited us from using CALL in language class such as our budget, university authorities towards the use of technology in the class, and the teacher attitudes along sides the CALL materials and others factors. This study will try to answer all these questions as well as investigate all the possibilities that might help in improving integration of CALL in the class. The study will provide some suggestion for further studies.

INFORMATION TECHNOLOGY AND MEDICAL STUDENTS AT SULTAN QABOOS UNIVERSITY

By

Akinyemi, A.; Al-Kindi, M.; Al-Rawahi, Z.; Al-Rawas, O.
Sultan Qaboos University
Post Office Box 39, Alkhoudh, PC 123, Sultanate of Oman
Email: akinyemi@squ.edu.om

Abstract

The present study was designed to investigate the medical students' readiness for web-based learning in terms of their information technology (IT) perception, computer literacy and accessibility to computer facilities. Sixty-five students (13 males and 52 females) were used in the study. Results showed that most students were favorably disposed and 95.4% of students were minimally IT literate. On their access to computers, there were many option, however, the university facilities ranked highest (90.8%) of all options. Many students (67.7%) are willing to take additional computer courses to benefit from the WebCT mode of instructional delivery.

Introduction

Sultan Qaboos University has embarked upon the infusion of technology into teaching and learning as a matter of policy through its adoption of the WebCT and other learning technologies. The College of Medicine is in the process of going online with a redesign of an aspects of its curricula in case based learning of the respiratory system to complement the traditional mode of instruction. Increasingly, people have come to realize that traditional instruction is not any longer adequate for contemporary Medical education practice. Similarly, it is inconceivable that traditional systems will be able to meet the needs of higher education in many countries, developed or developing. Distance education will indisputably be the recourse of higher education to satisfy the increasing need of this sector. Education anywhere, anytime, has been made real through the virtual learning technologies which have revolutionized the practice of many classrooms in many institutions.

Technology is consciously proffering solutions to educational problems in all sectors. Rapid advances in networked communication and the relative ease with which the "hypertext" media can be created are revolutionizing distance learning programs and such programs are becoming a normal part of the education practices of many universities (Schair and Kruegar, 2001). E-learning is a growing concept in higher education and its activities are the consequence of the advances in media technology. Web-based learning is not only ideal for learners at a distance but also offers a range of learning opportunities for full-time, on-campus undergraduates (Ryan et al. 2000). Grabinger (1996) calls for a number of strategies to adopt the new assumptions about thinking, learning, instruction and achievement that can lead to rich learning environment for active learning (REALS Educators and the proponents of computer-based education therefore need to ensure not only an environment that is conducive for active learning, but also one that is minimally susceptible to distractions that prolong learning time. The College of Medicine at SQU has put a case-based learning in respiratory system course online to complement the usual face-to-face, traditional education. Many other benefits accrue from e-learning as evidenced in Akinyemi, et al, 2002.

Objectives of the study

The objectives of the study were to assess S perception and attitude to IT, present level of computer literacy, and rate accessibility to computers and computer facilities (Labs and Internet Cafés).

Results and Discussions

Sixty-five students (13 males and 52 females) in the fifth year of College of medicine completed the questionnaire out of the ninety served (72% return). Results and discussions are presented in three categories according to the objectives of the study.

Perception, Attitude and Feelings about Computers

Figure 1 shows results relating to the affective dimensions of the study on the medical students' perception, feelings and attitudes toward computer learning. On the whole, S were generally positive in their attitude to computer learning as evidenced by the 61.5% negative score on 'dislike for computers' and the 67.7% score on the willingness of students to 'take additional courses in computers'. However, responses to items relating to their preferences for 'conventional teaching' (50.4%) and 'live lectures' (66.1%) suggest the need for proper orientation of students before the full scale adoption of e-learning.

Computer Literacy and Awareness

Figure 2 shows the present level of S computer awareness and literacy. A total of 95.4% responses indicated that they had used computers before and over 57% indicated that they had taken computer related courses. Except for e-commerce, S had used computers for 'chats, email, e-voting, e-discussions, Internet, and minimally for teleconferencing, and web-conference'. While probing further into S proficiency in computer use, it was found out that their expertise was limited to basically word processing. Students' Internet and email use seem to be most predominant with less than 20% claiming to be totally ignorant and unfamiliar with these two computer facilities. This finding has further been confirmed by the fact that over 43% of the medical students respondents have e-mail addresses.

Accessibility to Computers

Figure 3 below shows S responses on the various ways through which they have access to computers. Data indicates that 35.4% own computers, 58.5% have access in their homes, 90.8% have access to University facilities, 53.8% have friends who own computers and 23.1% can have access to Internet Cafes on the commercial basis. This item is especially important in view of the limited access of S to University computer facilities because of the large S population and high demand for the Computer laboratories. Other possible local sources like the commercial Internet Cafés scattered in major cities of Oman will complement the institutional facilities to make web-based education viable at SQU.

Conclusions

In investigating the readiness of S in the College of Medicine to engage in e-learning, student's attitude and level of IT literacy, are crucial for success in the proposed new web-based medical curricula at SQU. The current low level of IT literacy by students and their willingness to take courses in computers, to boost e-learning underscore the need for curricula modification to include basic skills in computers early in the S university program. However, S preference for the traditional face-to-face instruction, based on the results of this study, will be the focus of further research and enlightenment activities. Responses to S access to computers/Internet Cafes has revealed the need for the University authority to improve on the available infra-structures in time for the implementation of the new web-based curricula.

Faculty Adoption of Technology: The End User as the Determinant

Ahmed Ali

Abstract

The article talks about the concerns of faculty regarding integration of technology into instruction. It is based on a study about a faculty training project at a Midwestern university's college of education. The faculty training project involved the mentoring of faculty by graduate students in Instructional Technology. Based on the training experiences and interviews conducted with some faculty members, their perceptions regarding technology and its adoption were examined. The six-month project was a one-on-one mentoring program of faculty by doctoral students in Instructional Technology under the supervision of the Director of the Instructional Technology program. The article reveals factors contributing to slow adoption of technology by faculty and provides recommendations for increasing integration of technology into instruction by faculty. The article concludes that for faculty to use and apply technology, training in technology should be provided before availing technology.

Introduction

During the last decade of the 20th century, there was a revival of the calls for education to meet the needs of society. Schools and colleges came under increasing pressure from society and from advancements in technology sweeping across the country. Not since Sputnik was launched had there been a need for educational institutions, particularly institutions of higher learning, to adapt to changes. At the core of this need was technology, notably computers and the Internet. There were calls for universities to incorporate technology into their programs so that they could adjust to events in a global society.

As the goal of educational institutions is to produce individuals who become productive members of society, administrators and teachers tend to use any strategy or tool that can help them accomplish this goal. Lately, technology's potential to improve learning has been recognized, and there is widespread incorporation of technology into teaching and, more importantly, into learning (Maier et al., 1998).

Various approaches have been utilized to help faculty use technology. From workshops and seminars to using technology students to help faculty adopt technology, increasingly effort is expended to encourage faculty to be an active part of this trend in educational institutions.

Methodology

As part of this effort to help faculty integrate technology into their teaching, I participated in a faculty training project at a Midwestern university. The faculty training project involved the mentoring of faculty by graduate students in Instructional Technology. Based on the training experiences and interviews conducted with some faculty members, their perceptions regarding technology and its adoption into the educational setting have been examined.

The six-month project was a one-on-one mentoring program of faculty by doctoral students in Instructional Technology under the supervision of the Director of the Instructional Technology program. Participant faculty had limited skills or knowledge of technology, and for those who had technology skills, the skills were fast becoming obsolete in the face of rapidly changing technology. The training involved skill development in technology and instructional design.

The training was conducted in a learner-centered, constructivist environment, where the faculty decided what and how to learn. The mentors were in place to help guide the faculty. Faculty participation was voluntary, and the training was individualized, attuned to each individual's needs and abilities.

As part of the preparation for the faculty mentoring, mentors had a 2-hour weekly meeting that provided a forum for preparation and sharing of individual mentoring experiences. A listserv was maintained where mentors posted weekly reflections on their sessions with faculty. This was useful, as it provided an overall picture of faculty attitudes towards technology, their technological skills and competencies, their adoption and use of technology, and their perceptions regarding the integration of technology into their teaching. As the mentor of one of the faculty members, I observed the activities of the faculty member during the entire mentoring sessions. This experience provided first hand information on the attitude and skills of faculty towards technology. Personal and situational interviews conducted with six faculty members provided information about their experiences, perceptions, and utilization of technology, both for personal and professional work.

Appropriateness

As faculty occupy a central position in educational settings, their views and ideas pertaining to technology integration are important. There is a need to justify the suitability of technology before it is embraced. Brackett (1998) argued that the benefits of technology might not be realized if appropriate designs and teachers' skills and interests are not in place prior to the introduction of technology. He posited, "it's a mistake to put technology at the center stage as we plan and execute educational reforms. Technology should hover shyly in the wings, ready to lend its power, but only as needed" (p. 30).

Brackett was in agreement with Gardner (1998) who proposed that prior to using technology, there should be a reason to consider the need and the way to use it and only thereafter should it be introduced. Gardner cautioned educators against blindly believing in technology as the solution to educational problems and as an aid to performance. He stated that "many technologies-from slide projectors to TV-have been touted as the solution to American education. Yet these technologies have had remarkably little impact on mainstream education. When plugged in, they are all too often simply used to 'deliver' the same old 'drill-and-kill' content" (p. 33). Technology should be put to use as and when needed, and faculty should greatly determine such use. Technology should not be introduced for technology's sake.

Faculty

Teachers are inevitably becoming part of the movement towards technology use in classrooms. To be able to actively perform and remain skilled, technology skills are increasingly becoming important (Valentine, 2000). Faculty play an important role in integrating technology into instruction. For faculty, incorporating technology means using it as a tool to effectively transmit information to students.

Faculty should not lag behind students in technology proficiency. Preservice teachers should show competency in current technology before they enter the field, while in-service teachers should undertake individual initiatives to update their skills, including participation in workshops and other in-service training in technology. But emphasis should be placed on the best ways to integrate technology with teaching and learning. Valentine (2000) reported the *Education Week* (1) survey found that training teachers how to incorporate technology into their curriculum was more effective for technology integration into the classroom setting than teachers simply acquiring technological skills.

Slow Adoption

The study revealed that generally, faculty members have demonstrated positive attitudes towards technology and its integration into instruction. They view technology as helpful to teaching and learning. They recognize the potential of technology, particularly computers and the Internet.

Faculty participants stated that technology is a significant learning tool that diversifies teaching and learning strategies, facilitates research by increasing access to resources, and increases communication between faculty and students and administrators. Although they were aware of the role of technology and its increasing adoption in educational settings, some faculty members displayed little enthusiasm to adopt it. Even for faculty who were very positive about technology, their use of technology did not match their recognition of its significance. Some faculty members used technology more for personal enrichment than professional development. Computer use was more common for email and Internet search than curriculum or instructional-related work.

Adoption of technology by faculty is slow (Olsen, 1999). A number of factors, including those identified below, contributed to the slow adoption. Many faculty do not have the skills to use the technology they are provided or required to use. With the aim of integrating technology into their programs, administrators ignore faculty's abilities, skills, and interests to use these technologies. This has led to machines lying idle in faculty offices or being underutilized. One faculty member stated that he used his computer once a week or once every two weeks only to read e-mail.

Lack of or limited technical support for faculty undermined widespread the use of technology by faculty. Although faculty were not given training before technology was provided, even for those who learned on their own, continuous support was limited when provided. An absence of a full-time technical support person dedicated to faculty or support persons not competent with the varying needs of faculty creates less interest for technology integration. Thus, it becomes difficult for even full-time faculty support technology specialist to be conversant with the multiple needs of the faculty; yet faculty are under pressure (albeit mostly indirectly) to use technology either from students or administrators.

BEST COPY AVAILABLE

Lack of confidence contributed to faculty's limited use of technology. Faculty were concerned that if they incorporated technology into their instruction, there was the possibility that students may know more about computers than the faculty. Teacher did not want to appear ignorant in front of their students. Possibilities of technical problems discouraged some faculty members from using the instructional lab of the college.

The fast pace of technology innovation did not augur well for its espousal. Two participants felt they did not need to learn about technology at this point of their career. As using technology requires continuous skill development, faculty found this to be time consuming. One faculty member said continuously updating technology skills consumes time that would be better spent on research work, saying, "If the technology I use today will be useless tomorrow, what is the point of learning it…I better spend more time on what I am used to than learning new skills, which are not only demanding but which I might not use." Several faculty members consider technology to be an add-on to their already busy schedules and commitment.

Being used to traditional instructional styles derailed efforts to adjust teaching styles to accommodate technology. Using technology as part of teaching and learning leads, in many instances, to change in instructional styles where there is more student involvement in the teaching and learning, with the possibility of eventually leading to learner-centered instruction, thus diminishing the role of the faculty. This possibility created resistance from faculty because they considered it a threat to their positions and indispensable status. Thus, faculty would prefer an old, didactic teaching style that guarantees the supremacy of their position rather than incorporate a tool that undermines this supremacy.

In planning for and adopting technology, there is the tendency for institutions to consider faculty needs to be secondary to that of students and staff. There was the perception that with regard to technology, faculty were not prioritized despite their status. A faculty member said, "When institutions gauge their level of technology use, they measure, for example, student-computer ratio," ignoring faculty. This perception created indifference, if not hostility, to technology by some faculty.

Limited concern for individual faculty needs in the provision and use of technology was an issue. Faculty are treated under one umbrella, without individualizing the needs, abilities and interests of individual members. There was the general assumption that hardware and software that worked for one faculty member also worked well for other faculty members. One faculty member posited she is using a Macintosh computer, which is not her preference but which has been provided to her, and thus she had no alternative but to use it. Another faculty member told me how "irrelevant" programs were taking up space on his hard drive that he never used or had no need for.

Another concern rose about the emphasis given to technology. Faculty viewed technology to be nothing more than a tool for teaching, just like the chalk. They could not comprehend why there was too much fuss about technology, complaining it was draining resources meant for research, faculty, and curriculum development. In scaling its significance, they considered technology to be supplemental to instructional and research activities and curriculum development. While recognizing the computer technology's potential, they stated technologies, like radio, TV/video, and typewriters, were used for a long time and argued that it has not created a "problem." On the contrary, they have happily incorporated them into their teaching.

Suggestions

The concerns of the faculty about use of technology call for reassessment of the current practices of technology implementation. To facilitate access to and use of technology by faculty, the following recommendations are helpful:

The current strategy of just providing technology without concern for the end-user needs to change. The focus should be the ability of users to use technology rather than providing machines, which might end up being idle shells in offices. Faculty should be trained to be able to use technology before it is provided.

Technology support should be provided to faculty. Technology support has often been limited to hardware support. Faculty require both hardware and software support, and faculty support personnel should be competent in both.

Faculty should have the freedom and the will to use technology in their classes. Administrators should not pressure faculty to adopt technology. This runs the risk of being counterproductive to student learning. Technology introduction should be gradual, without hastily introducing faculty to technology that they do not comprehend.

Faculty technology centers would be ideal if faculty are to comfortably use technology. This would provide a forum for faculty to share their experiences and learn more about technology that is not available in their offices. In the past, faculty members were not comfortable using technology centers because they did not like to mix with students and staff in such centers. Where faculty-only centers might not be feasible, online support, discussion forums, and listservs dedicated to technology issues could be set up for faculty.

There is a need for greater institutional support. For proper technology integration, administrator backing and support for faculty is crucial. These include employing adequate technology assistants, allowing as many faculty members as possible to sit in technology committees, ensuring technology does not take away resources from faculty research activities, and allowing for greater flexibility in instructional styles and curriculum to accommodate individual teachers' needs and concerns.

Conclusion

Use of technology by faculty at colleges, though increasing, is not widespread. Many faculty members lack the opportunity, training, or motivation to use technology. Adding on to this situation is the unplanned provision of technology while training in the use of this technology is limited, if not lacking. Faculty members' limited use of technology has primarily to do with technical, personal, and instructional factors, which, if addressed, can increase technology use by faculty. Most important is that for technology to be successfully used by faculty, there is a need to change the focus from providing technology first to training faculty first. Whether it will be used for instruction or other purposes, the end user should determine whether and how technology is used.

Teaching the Course “Introduction to the Information Society” at the University of Cyprus: a Pilot Methodology.

Panagiotes S. Anastasiades
University Of Cyprus,
Department of Computer Science
Cyprus
Vice-President of the Permanent Scientific Committee on Social Issues of the Greek Computer Society
panas@ucy.ac.cy

Abstract: The introduction of the course “Information Society” by the Department of Computer Science at University of Cyprus, aims at familiarizing the students with one of the most important priorities of the European Union at the beginning of 21st century. This work contains an analysis of the necessity, the targets and the key points of the course to be introduced. Our attention will be focused on the development of a hybrid learning model, which will be based on the optimum combination of open and distance learning, the development of an interactive internet site and conventional teaching.

Introduction

In an era that everything around us is changing at incredibly fast rates, the contemporary human being as well as the social structures that he has built during the ages, are trying to cope with the new demands that are being created. Computers (P/Cs) are at the peak of technological development, as they constitute the most characteristic advanced party of the new age. The basic relationship between the human being and information is reversed (Anastasiades, 2000a, p. 22). The information nowadays travels through networks towards people who are looking for it from a fixed geographical point via their personal computer. Over the last years the Information Society has been one of the primary issues on the political agenda of the European Commission (COM(94) 347/2 final). The Information Society is based on the informed citizen, on the person who knows the advantages and the challenges of the new era, as well as the ways with which he will seize the opportunities which will be presented to him (IST, 2000). The introduction of information and communication technologies into education significantly changes the structure and operation of education as it has been until now (Berge & Collins, 1995). The basic relationship between educator – learner is reversed (Anastasiades, 2000b), as through electronic networks the educational process is transferred to learner's private space, no matter how many kilometres separate the learner from the educator. Through teleconferencing learners can attend organized units of classes and lectures from anywhere they choose and are able to intervene, to ask questions, to exchange notes, reading lists, etc. With a PC and the necessary multimedia applications, a learner can participate in the educational process, acquire knowledge in which he is interested, evaluate his learning ability or even be evaluated from the distance learning centre which will be able to certify his/her knowledge (Ellsworth, Jill H. (1994). A hybrid-learning environment is one in the context of which we try to combine in the best possible way new technological applications – that set the educational procedure free from its ties in time and space – and the respective pedagogical references to the basis of the traditional educational procedure school of thought [http://www.cs.ucy.ac.cy/~panas/UCY/EPL011-IS/AA_Home_IS.htm]. The hybrid learning environment is a conceptual and functional integration of traditional educational methods and new modern approaches.

Working out the teaching methodology

The proposed course will attempt an extensive and in-depth presentation of the Information Society (IS) framework being formed up. Expounding in full all those factors that will help record and demonstrate the size and importance of Information Society will be our first priority. Objective of the first instructive part is to provide the necessary outline of subjects that will assist the students get familiar with the concepts of IS. The audience gets familiar with concepts like the electronic government, open and distance learning, teleworking, new economy, digital enterprise, electronic commerce, telemedicine, digital TV etc. The teaching of the course “Introduction to Information Society” is based on a teaching methodology which is part of the endeavor to implement – under real circumstances – a hybrid learning model with the characteristics we described above. The whole endeavor is based on the optimum combination of the main characteristics of the conventional educational environment, the educational aspect of the Internet and the asynchronous transmission in an Internet environment.

The implementation of this pilot endeavor follows these steps:

?. Preparation – familiarization of the students: Practically none of the students who attended the course was experienced in the use of the new educational technologies in their curricula. Their familiarization was therefore deemed necessary, and was achieved by readjusting the arrangement of the course.

Meaning, the philosophy and the sequence of the first series of lectures were primarily directed to the requirement of getting the audience familiarized with the basic characteristics of the new educational environment.

?. Development of an Internet site for the course: the students were fully familiarized with the use of the Internet as a means of information and communication in relation to their courses. Additionally, they were encouraged to use the pages of the course on the Internet [12], where, in addition to educational material, bibliography and useful links, they could see and download the lecture slides, create virtual chat rooms etc.

C. Development of pilot videotaped courses: once the teaching of the subject "Learning and Information Society" was complete, the audience was properly prepared to work under real conditions, experiencing the concept of the learning hybrid environment. The lectures for two subject parts were videotaped this way, and the students could see them by visiting the page of the course on the Internet.

D. The teaching methodology worked out provided the following: The students attend the videotaped delivery of the course through the Internet, which substitutes a scheduled lecture in the amphitheater. The students attend the course at the place of their choice, e.g. from the lab or their house, at a predetermined period of time, e.g. two days. At the end of the videotaped course delivery, the students were supposed to undertake certain assignments (in the form of questions and subjects given by the instructor), which they would present to the class at the next scheduled lecture. Thus, there would be enough time for discussions, presentation of studies and interchange of different views and approaches.

?. Evaluation Methodology: A model for the evaluation of the hybrid learning methodology is developed at three levels: Exante, Ongoing, Expost. Students and instructors record the pluses and the minuses of the whole endeavor, suggesting alternative methods and approaches.

F. Evaluation of Students: The evaluation of the course includes three stages: The first stage includes the carrying out of a major assignment by groups of students on subjects related to the course. On the second stage, there will be an evaluation of short research endeavors following the videotaped lectures. At the end, the grading of the students gets finalized once they take a written final examination.

Conclusions

As part of this work, we saw a presentation of the most important steps for the establishment of a hybrid-learning environment at a pilot level. The characteristics of the new teaching model can be summarized as follows: The classroom ceases to be the principal place where knowledge is transferred from the teacher-transmitter to the student-receiver, and is transformed into an open and creative place for discussion, pursuit and combination of different scientific approaches and views. The instructor, not having to worry about covering the material to be taught, will be able to act undistracted as the coordinator of an educational environment of unlimited scope. The students will experience their participation in the classroom as active and leading elements of the educational process in its new form. The page of the course on the Internet changes from an area of updating, communication and information to an area of instruction through the use of asynchronous transmission techniques.

A Swedish net-university – visions of desirable societal developments

Mats B Andersson

Media Technology and Graphic Arts, Royal Institute of Technology (KTH),
Lindstedtsvägen 5, 10044 Stockholm, Sweden,
tel.: +46-8-7906000,
e-mail: mba@nada.kth.se or mats.b.andersson@ilu.uu.se

Proposal

The paper presents a study of the Swedish net-university established in 2002. The organisation is in its infancy and is very much in a vague shape. A public authority was established 1 mars and the beginning of educational activity is planned to the autumn semester, according to political statements.

The Swedish net-university is not a new seat of learning; it is just an organisation that promotes and coordinates other universities network distributed education. It is to inform and market courses by a web portal, develop network supported distance education and generate more knowledge and experience in that subject.

This study has a focus on ideas on the emerging organisation, its aim and purpose. Politicians and member of the board in the authority, what thoughts do they have? What visions do they have? In what sense can this organisation support flexible education? What task should the Swedish net-university have in the Swedish academic infrastructure? What emerging needs is it supposed to be a solution of? The research is grounded on statements, by studying documents, letter of intent, and structured and open-ended interviews.

Assessment of Understanding: a Case Study

Abstract: Testing is being increasingly used in elearning settings at higher education institutions. Computer Assisted Assessment (CAA) is seen as having limited skills testing and assessment possibilities. In this paper an innovative use of the TestTool for assessment of skills and understanding is discussed referring to assessment practice in "Data Structures" subject.

Introduction

Testing is being increasingly used in higher education institutions. It is seen as appropriate way for assessment knowledge acquired in knowledge-based subjects with recall and recognition skills predominating. Technical and technological studies are based mainly on knowledge building via the real understanding how process or construction works as a whole. The real understanding comes up through achievement of certain level of subject knowledge, as well as through developing skills. Computer-Assisted Assessment (CAA) environments currently in use help mainly to assess level of knowledge, but have limited skills testing and assessment possibilities.

What we are seeking is a means of assessment appropriate for learning through knowledge building. In other words, we look for a means to provide a possibility for students to manipulate with subject mater elements, to trace students' actions during their manipulations and to assess their capabilities according to the task solved. We made an attempt to approach this problem by developing our TestTool, which was designed at Kaunas University of Technology as web-database e-learning system for self-learning and assessment.

In this paper an innovative features of the TestTool are discussed - an authoring and use cases of so called 'graphical construct' question type, which extends the TestTool functionality beyond a typical testing of knowledge but allows to view assessment as a step of knowledge building and testing for understanding. The TestTool usability has been investigated in class experiments delivering "Data Structures" module for CS undergraduates.

A Point of View on Testing Question Types

The range of question types being used in CAA settings is rather narrow with a great predominance of multiple choice questions (MCQs). Because the ease of realization, there are numerous CAA systems, which employ a set of question types aimed at recalling, matching terms or simple concepts, filling gaps, etc. But, such a question types, though realized through different interfaces, have a similar formative influence on learning outcomes as MCQs.

We think, that the only way to achieve academical credibility of testing at higher education level lies in radical changes and introduction of new forms and types of test questions. Obviously, that leads to the construction of new CAA engines capable to analyze and evaluate the more complex forms of answers provided by students. Such systems certainly are more complex in terms of implementation, authoring of test questions, usage, maintenance and so forth. But, along with advancements in ICT there is no other way than to distinguish between the use of technology for knowledge construction versus knowledge memorization and reproduction.

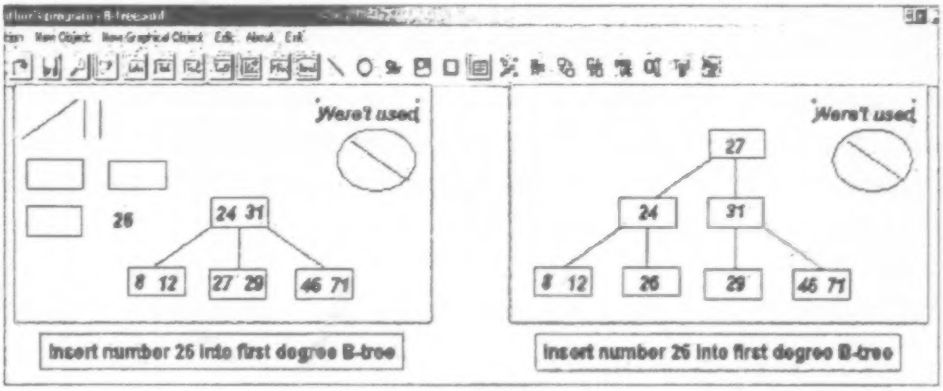
The TestTool assessment engine, along with traditional types of questions, is capable to deal with a new question type addressed to assess real problem understanding rather than recalling and looking for correct answer among a few predefined alternatives. We call this type of question as 'graphical construct'. The concept of the 'graphical construct' question is in giving a student a task to create or assemble a correct construction from a set of objects spread in constrained area on the screen, called a 'graphical panel'. The content of a test question is to build up a correct construction from the objects given within the panel, avoiding a selection of the correct answer from the predefined ones. Behind the scene there is a fully correct construct created by the subject author, which is used by assessment engine when student submits his answer version.

A software engineer having a task to implement the concept of the graphical construct question actually must find out a compromise between realizability and meaningfulness of test situation. In other words, it is a trade-off between meaningfulness of the test question and possibility to check automatically the correctness of the answer to it. We came up to one such compromise in the design of graphical construct question.

Tests for "Data Structures" Module: a Case Study

TestTool has been used when delivering "Data Structures" module at KTU. Within that module we take a basic data structures and explain data processing using various graphical representations. Our intention is to stimulate reasoning and to assist students in understanding data transformations when dealing with various data structures, and also to have an ability to assess their learning outcomes. We are going to show how graphical construct question could be used to create test situations, which require students to demonstrate reasoning activity in order to design a correct answer, and therefore such a testing can be interpreted as testing for understanding.

As an illustrative example we take a task of insertion of a new element into B-tree retaining it's consistency as a B-tree. By making use of graphical construct question we came up to the following instructional design, which is rendered by task authoring interface on Fig. 1. The display is split into two parts: left-hand side is a graphical panel area where question or task situation should be created, and right-hand side is correct answer area. Both must be created by author. When saved, they are stored separately as XML files in a database. Taking a test student receives only a task situation and is asked to construct his answer using a set of given elements and to move all unnecessary elements into the 'Weren't used' area.



Insert number 26 into first degree B-tree

Insert number 26 into first degree B-tree

Fig. 1. Task situation and it's solution (author's view)

Depending on initial Btree and element to be inserted, the insertion may cause a re-building of the tree caused by overflow, which in turn may cause recursive overflows, split and growth of a tree up to the root. Comparing the task situation on the left and anticipated answer on the right, one can see that student must accomplish a sequence of constructive actions in order to build a correct answer. It should be anticipated, that there are rules and heavy restrictions on actions to be done. Only owing to that, however, the correctness of answer can be checked automatically by the TestTool engine.

A number of task-solution situations, along with MCQ type questions, related to a certain data structure like Ordered and Orderable Lists, Stacks, Queues, Binary Trees, AVL Trees, B-trees, Hash Files, Index Files have been created for "Data Structures" module. Referring to the results of self-testing and final assessments carried out in real conditions of module delivery for a two flows of students during two years we do argue that TestTool graphical construct facility, if used with meaningful instructional design, allows us to test and assess students for real problem understanding. Such an opinion was pointed out by many students.

Online Writing as a Form of Electronic
Communication in a Second Year Biology Course

Michael K. Barbour and Michael A.J. Collins
mbarbour@nf.sympatico.ca / collinsm@mun.ca

Memorial University of Newfoundland
St. John's, Newfoundland, Canada A1B 3X9

Abstract - This paper considers student use of an online discussion forum in a second year Biology course and how that participation may be an indicator of increased student success in the course. The authors discuss how participation in the online discussion forum is a form of public writing in which the students need to have an understanding of the topic about which they are writing. It is this practice of writing with a clear understanding that may increase students' success in the course and not simply the use of online communications.

Introduction

One area where computers have made a significant impact is in the realm of computer-mediated communication or electronic messaging. According to Zack (1995), the term electronic messaging includes "several modes of computer-mediated communications, including electronic mail, electronic talk or chat, computer conferences or bulletin boards, and electronic document exchange." (p. 206) This definition is very broad in its scope and for the purpose of this study, electronic messaging will be limited to electronic mail, messages sent to an electronic listserver, and posts to a web-based discussion forum.

The course considered in this study was Biology 2040 – Modern Biology and Human Society I (Human Biology), a large enrolment second-year, non-major Biology courses which is regularly offered in on-campus lecture, off-campus correspondence and Web-based formats. During the period 1997-1999, student contributions to a Web-based discussion forum and e-mail messages sent to the instructor were collected. An analysis of these data was undertaken to determine whether or not a relationship existed between the use of electronic messaging and the final course grades of the students. A comparison of the performance of students in the different instructional formats of Biology 2040 is described in Collins (2000a).

Student Achievement and Electronic Messaging Usage

Collins (1995) found that the electronic bulletin board had fostered "student-student interaction and student-professor interaction… of course student-professor interactions through computer conferencing will never be a total replacement for face to face interactions, but computer conferencing does provide another channel for such communication." (p. 189) More recently Collins (2000a) illustrated that while there was hardly any difference between the final course scores of e-mail users and non-users, there did seem to be a positive relationship between the level of web forum use and final course scores.

Collins (2000b) found that in the web-based version of Biology 2040 during the Spring 1996 semester, there seemed "to be a relationship between the level of web forum use and final course scores." More specifically,

> that very frequent users achieved an 'A' for the course while frequent users achieved 'B's. It is interesting to note that those achieving 'C's and 'D's in the course were either infrequent users or did not post notes to the forum at all. None of the three students failing the course posted notes. There is, therefore, a relationship between web forum use and final course scores with very frequent users achieving higher marks, while students not using the web forum are more likely to fail. (p. 7)

The results in this study based on a larger number of students reinforced to those found in the previous study.

Since this earlier study examined just one individual class, the present study included all classes for which we had had during the period 1997-99. These data are illustrated in Table 1.

Table 1 - Frequency of use of the web forum and final letter grade

	Course grade				
Level of use	A	B	C	D	F
Very frequent	2	0	0	0	0
Frequent	1	2	0	0	0
Infrequent	18	10	4	1	2
None	21	17	7	2	4
Totals	42	29	11	3	6

Unlike the relationship between the letter grade achieved and the level of electronic mail use, which is discussed in Collins and Barbour (2001), this table indicates a clearer relationship.

> [Table 1] shows that the relationship between the letter grade achieved and the level of web forum use is even clearer than for e-mail use. Only 'A's were very frequent users, and only 'A's and 'B's were frequent users. Only about one third of 'C's, 'D's and 'F's were infrequent users while two-thirds made no use of web forum. Students achieving an 'A' in the course were much more likely to be web forum users (21 of 42) than 'B's (12 of 29), who, in turn were more likely to be users than 'C's, 'D's, and 'F's (only 7 of 20). (p. 7)

Both this study and Collins (2000b) lend credit to the notion that students who participate in online discussion forums have a greater chance of success in the course than students who do not participate.

This notion may be explained by findings from two different areas of research. Over a decade ago, Chickering and Gamson (1987) put forward the concept that interaction is a key mechanism in enhancing learning. This concept could be applied to this study if one were to include electronic messaging as a form of interaction. However, a second area of research may prove a greater relationship. There is a growing body of research that indicates that students who write about their subject learn that subject better. One such piece of research is Moore (1993), who has shown the connection between writing in Biology and higher course scores as others have demonstrated for other subject areas.

Collins and Barbour (2001), speculate that while email messages are often short messages about non-content queries which are 'private' and only for the instructor's eyes, postings to the web forum are 'public' and open to the scrutiny of all class members. Students are more likely to be careful and deliberate about what they write on the web forum because they are for public consumption. (p. 8)

Conclusion

While there was no apparent relationship between the use of electronic mail and student grades, this study found a positive, but not conclusive, relationship between the number of times students posted to the web forum and the grade that the student received. Students who received 'A's and 'B's in the course were more likely to be "frequent" or "very frequent" users of the web form, while students who received 'C's, 'D's and 'F's were more likely to be "infrequent" or "non-users."

The positive relationship with posts to the web forum and not electronic mail seems to confirm the assertion by Chickering and Gamson (1987) and Moore (1993) that interaction and public writing are key mechanisms in enhancing learning. This is based upon the premise that contributing to a web forum is a carefully planned, deliberate writing activity on the part of the student.

Abstract: The purpose of this study was to determine if student satisfaction would increase with web-enhanced instruction. This study was conducted at Lamar University, Beaumont, Texas, USA, during spring 2001. Two courses relying upon slide presentation, Architectural History and Art Survey, were selected for the study. Combined enrollment was 48 students. The first half of the semester was taught in the traditional manner. At mid-semester a questionnaire was administered to determine student satisfaction with the traditional method of teaching. Then students were given access to a web page containing the remaining semester slides (visual images) and instruction about accessing the web page and progressing through the visual images. At the end of the semester, another questionnaire was administered. Both questionnaires revealed 53% were satisfied with the teaching method. Although an increase in student satisfaction was not detected, a majority of the participants expressed a positive opinion of having visual images on a web page. Each instructor, encouraged by students' responses, decided to enhance other courses by providing visual images on a web page.

Introduction

In 1990, only a decade ago, the Internet was a virtually unknown concept, beginning as a communications link among computer facilities (Teh, 2000). However, with the development of user-friendly software, a new era of communication technology emerged for the masses. Internet technology has been compared to the invention of Johann Gutenberg's movable type. Not only has the cost of information distribution been driven down but the wealth of knowledge shared has increased a thousandfold (Wallin, 2000). The fact that we are now able to connect distant peoples, assemble and use diverse learning resources, and provide enhanced access to educational opportunities is more powerful and far-reaching than we could have imagined a decade ago. Educators are now incorporating resources that the Internet has to offer, adding web-enhanced instruction and/or web-based instruction to traditional classroom pedagogy.

Problem Definition

Traditionally, in courses that require viewing slides projected in a classroom, many students have experienced frustration when attempting to listen for important information, write notes, and hurriedly sketch images to remind them of the slides. In addition, not having slides conveniently available outside regular class hours has hindered the review process, and may have negatively affected student performance on exams. Web-enhanced instruction could provide solutions to these problems and increase student satisfaction. If it could be shown that web-enhanced instruction increases student satisfaction, instructors may be receptive to incorporating this technology into their teaching methods.

Methods

The subjects invited to participate in this study included students enrolled in two courses: Architectural History and Art Survey, for the Spring 2001 semester at Lamar University, Beaumont, Texas. Course content depends on students viewing images from slides projected in the classroom. Students are tested on knowledge retained from lecture material pertaining to these slides.

Two instruments were used to determine student satisfaction. The first, administered at mid-semester, collected demographic information and assessed student satisfaction with traditional course delivery and content. A web page was created and made available to students for the second half of the semester. The web page contained the remaining semester visual images. At the end of the semester, student satisfaction with course delivery and content was determined using a second instrument. Ratings from the two questionnaires were compared, using students' t-test for correlated groups. StatView (SAS Institute, Inc., 1999) was used for data analysis.

Results

All 48 students indicated that they had access to a computer and the Internet. They also indicated that they had experience accessing Internet web sites, web pages, and email.

Several items on the questionnaire were used to measure overall student satisfaction: 1) interest in the class, 2) willingness to recommend the course, and 3) level of satisfaction. Both the pre-questionnaire and post-questionnaire revealed that 53% of participants were satisfied with the curriculum. A majority (68%) of students agreed that the web page enhanced the effectiveness of the educational material and lecture. Approximately 75% of those responding agreed that learning and retention was enhanced by accessing the web page and that the web page benefited learning. On the post-questionnaire, 42% of students agreed that access to the web page allowed them to concentrate more on the lecture in the classroom. One-fourth of the participants indicated that their grades improved with the addition of the web page.

Course instructors were optimistic about incorporating a web page into their curriculum, and felt that having this resource available would have a positive effect on student learning. This study provided an opportunity to incorporate technology into the classroom. Both the instructors and students were pleased to have this option available to them. As the new semester began, each instructor acquired assistants to have visual images from their other courses incorporated into web pages.

Topic: New Roles for Teachers/Learners

Title: "From Campus to Cyberspace: The Transition of Classroom Faculty to Distance Teaching Roles"

In an increasingly digitized society, the role of faculty is undergoing profound change, As more teachers make the transition from the classroom to technology-assisted mentoring of students at a distance. How are these faculty making this shift, what is their perception of their new roles, and what do their colleagues and students think? A study of fifty faculty teaching distance education courses at six institutions reveals useful information and offers valuable insights for both administrators overseeing these shifts in instructional roles, as well as for teachers involved adapting to the change from face-to-face relationships with students to mentoring academic progress of learners they may never meet. The survey reveals that while those making the transition are generally satisfied with their new roles, and feel their students recognize their contribution as distant educators, their classroom-based faculty colleagues continue to view distance education with skepticism. There are no more dramatic phenomena taking place in higher education today than this shift in how institutions and their professoriate provide education across time and space.

Biography: Michael F. Beaudoin, Ed.D. is currently Professor of Education at the University of New England in Maine; where he serves a faculty mentor in a distance education masters degree program.; he also is an online adjunct faculty for Carl von Ossietsky University of Oldenburg, Germany, where he maintains a research/writing collaboration with colleagues at the Centre for Distance Education. He is recognized for developing numerous innovative academic programs utilizing alternative instructional approaches to serve adult learners, including successful distance education programs at two institutions. He is actively engaged in research, writing, presentations, evaluation and other professional activities relating to the field of distance education.

Young Adult Literature: Creating an online companion to an on-campus course

H. Timothy Blum: Albany Co. School District, University of Wyoming Lab School, Laramie, Wyoming, U.S.A. tblum@uwyo.edu

Dr. Barbara Chatton: University of Wyoming, Professor College of Education, Laramie, Wyoming, U.S.A. bchat@uwyo.edu

Dr. D.J. Yocom: University of Wyoming, Chair Department of Special Education College of Education Laramie, Wyoming, U.S.A. djyocom@uwyo.edu

Abstract: The task of creating an online course that mirrors the content material found in on-campus course offerings is difficult, but allows students constrained by distance and time to take advantage of courses required for advanced certification. Care must be given to present the material in a manner so that students with diverse abilities and learning styles will be able to benefit from the content information. The course must promote student / instructor, as well as student / student interaction.

Text:

Wyoming is a huge state with a small population and one four-year College located in the extreme Southeast corner of the state. The difficulty of travel, time involved, and cost make online learning practical for many Wyoming residents. In the last three years the UW Outreach enrollment has increased by nearly 50%, during that same period of time online enrollments have increased almost five fold (University of Wyoming Outreach enrollment report 2002).

Teachers in Wyoming represent a group for which continuing education is required for re-certification. Reliable online instruction has a certain appeal for teachers who cannot readily travel or have difficulty in scheduling blocks of time required for on-campus course offerings. Online course offerings allow students to enter the classroom at their convenience, eliminate the need for travel and time related expenses, and allow students to participate in content related questions while by-passing the ritual and ceremony surrounding social interactions in face to face gatherings (Pinch & Graves, 2000). Using computers to deliver content material to students is cost effective, but still requires instructors who can adapt dynamic classroom conditions and maintain a flexible approach to different student needs (Hooper & Hokanson, 2000).

Online courses must offer more than convenience. Robust online courses make allowances for individual learning styles and levels, encourage learners to apply new content material to their existing knowledge, create opportunities for students to interact, and build relationships (Morgan, 2001; Pinch & Graves, 2000; Rutter & Matthews, 2002). Successful online courses involve students in building cohort relationships through interaction and allow for self-paced learning (Kimball, 1995; Pinch & Graves, 2000; Rutter & Matthews, 2002). Effective online courses address the needs of individual students, provide content material appropriate for students, summarize and synthesize information, and allow feedback (Kimball, 1995; Rutter & Matthews, 2002). Online courses will not replace campus based courses and face-to-face interactions with teachers, but they will augment university offerings. For computer based courses to be effective there will need to be an effective instructor who can adapt classroom conditions, in an electronic medium, and demonstrate flexibility in the face of diverse student needs (Hooper & Hokanson, 2000).

In order for an online course to be effective it must involve the student in many activities that are present in face-to-face instruction, dialogue, feedback, scaffolding, and activities that promote the application of knowledge to new situations. Offering a successful online course in Young Adult Literature requires content material that addresses the effective elements of computer based instruction mentioned above, while giving the student an opportunity to engage in discussions that build on their base of knowledge. This application of content material to an individual's real life is one of the major advantages found in a literature circle discussion format used in the face- to-face classroom (Blum, Lipsett & Yocom, 2002; Daniels, 1994) and built into the online version of the course. Other activities require students to respond to threaded conversations, respond to colleague responses, make reflective journal entries, and take part in real time chat rooms to discuss Young Adult Literature.

At the University of Wyoming the Young Adult Literature course was designed to utilize the online format employed by the Outreach School. The course was also designed to address the content material covered in the on-campus version of this course. The challenge has been to use the e-college format to provide content material to students while promoting discussion, reflection, and construction of new enhanced knowledge bases for teachers interested in learning more about Young Adult Literature for use in their classrooms.

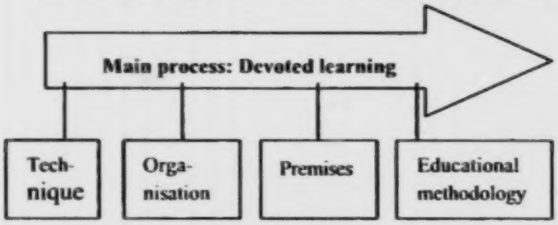
Evaluation of the VR-project In Helsingborg, Sweden

Authors: Hans Espling, Lennart Bolin, Lena Hannersson, Kersti Adler, Kristian Lindgren,
Irene Lundmark, Claes Rube, Magnus Johansson, Fredrik Hansson
Authors Affiliation: Project team at the Local Education Department
hans.espling@gy.helsingborg.se
lennart.bolin@komvux.helsingborg.se

Abstract
During the school year 2001 – 2002 a project team is working with a project with the aim of delivering a virtual unit for the comprehensive upper secondary school in Helsingborg.
We are in the middle of the implementation phase and the project will be at its end in the beginning of June when our students have completed their courses and received their certificates.
We have defined a number of deliverances, which the overall purpose of the project is divided into. In the report (see http://www.learnit.helsingborg.se/) we have delivered descriptions of the educational methodology and a proposal for an operating organisation. We have carried out a market survey but have adopted a "wait and see plicy" when it comes to market strategy. The project-team has consciously chosen not to take a decision on a technical platform, in the purpose of avoiding the project becoming a "technical project". Instead we have unprejudiced tested different technical environments. We also deliver four courses; all of them ready to start. Furthermore the report contains a description of premises needed for the e-school.



Example of supporting processes

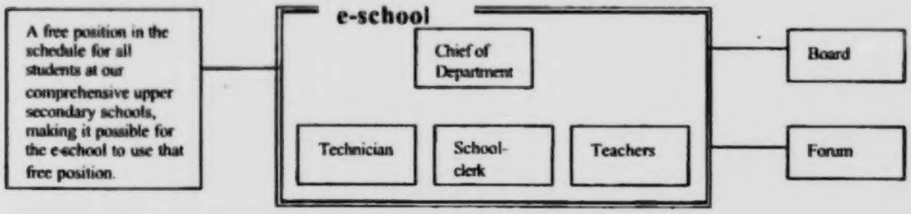
Key terms in educational methodology

1. Educational methodology

The main factor for a successful e-school is that the pedagogy is formed and adjusted according to the conditions. The experience during the project is that the pedagogical basis is the same in flexible learning as it is in all other forms of educational methods. What is important in planning and realization in this form of education is to develop a procedure in such a way that we estimate how a number of key terms will distinguish the education. During the project period a number of such key terms have clearly been crystallized (see figure above). So the experiences are that flexible learning demands flexible education and that we pay great attention to the key terms in the figure when we create courses and educational packages for the e-school.

2. Operating organisation

The e-school is meant to be a special unit, under the Local Education Department, where all students at our comprehensive upper secondary schools must have opportunities to study. It must be established that students will only be studying separate courses at the e-school. The student still belongs to the school where he/she has a regular place. Teachers connected to the e-school shall have most of their duties at their ordinary school and a smaller part at the e-school. In order to make the e-school work there must be a distinct organisation. The team-group suggests that a small but powerful organisation is created as follows in the figure:



A free position in the schedule for all students at our comprehensive upper secondary schools, making it possible for the e-school to use that free position.
e-school
Chief of Department
Technician
School-clerk
Teachers
Board
Forum

BEST COPY AVAILABLE

3. Market survey

In the local school-debate and in the document "Engaged Learning for everybody" from the local school committee, there are a number of demands for an increased possibility to choose courses and to create more individual education. In January 2002, we made a market survey among students in Helsingborg (upper secondary level) with the purpose of investigating whether the wishes from the students have been fulfilled. Our investigation, done in cooperation with the HELGE-group (a group for contacts between students and the schools), shows that about 30% of the students do not have the possibilities of studying the courses they want to. Up to 57% of them say they have not the possibilities of studying at their own speed. A realization of the aim of the VR-project is a solution that will provide for the requirements from the students.

4. Market strategy

If the government committee of Helsingborg decides to start an e-school, there will be an immediate need of marketing the e-school. The information should be directed towards the following main groups:

- pupils and students at lower and upper secondary school
- parents
- study counsellors
- headmasters
- teachers

The information can be spread through existing channels of communications since the courses offered by the e-school is also the courses offered by the regular school. Other groups in the society can also use an e-school and the information shall therefore also be spread to companies and organisations.

5. Premises

One of the ideas with the e-school is to make the education independent from *time* and *space*. On the other hand, as our experiences from the project-period points out, it is out of the question to run this type of education on upper secondary-level without "face to face" contacts. We will make it clear that our experience is that it's necessary to carefully plan the amount and regularity of meetings with the students. How "the face to face" contact is organised depends on the aim and plan of the course

The project-team wants to make it absolutely clear that one of the conditions for success is that an "e-school centre" is created. The students must know where the school is situated, in the real world as well as on the web. That's where they know they can get help with their studies. There's also an important social aspect from the students point of views.

The experience is also that it takes a lot of cooperation between teachers in order to get the concept working. An e-school centre would work as a natural place of meetings for teachers as well as students.

6. Summary

After a short acquaintance with the concept we call e-learning, you may think it's a school that is completely virtual and a place where the students are hanging over computers in order to learn the contents of a course. But the e-school we intend to build is neither such a school nor a school for only distance education. No, it will be much more than that. It will be, on one hand, everything from electronic support in the traditional education for all students at one time, till on the other hand, an advanced concept on a web site where most of the course is available. As an overall theme we have the principle that there must be a number of social contacts between students in every course.

It's also important to be aware of that e-learning works all right for most of the students if it is made the right way. For a smaller group of students this way of educating is less suitable. The market survey shows a great interest for this form of education and it is maybe realistic to think that 10% of our students will study a course at the e-school during his/her stay at the upper secondary level. In order to get an overall structure of the e-school there is a need of a joint basis. This consists of a shared view on educational methodology, a distinct organisation, an e-school centre and a technical platform. A decision to launch an e-school is also a decision for this basis to be built.

Good effects that we did not see at the beginning of the project-period are that a good platform for cooperation has been created with teachers from the different schools. A cooperation across the borders of subjects has also taken place, when methodical aspects have been the common factor. The courses must be analysed in every detail when adjustment to e-learning is done. Experience shows that the e-school can work as a bridge between schools and groups of teachers.

Designing and redesigning the WebCT part of the undergraduate course "Teaching and Learning with Music Technology"

Marie-Michèle Boulet
Full professor
Faculty of Music
Universite Laval
Casault building #3312
Quebec, CANADA G1K 7P4
marie-michele.boulet@mus.ulaval.ca

Abstract

This paper describes the content of the first release of the undergraduate course MUS-19673 Teaching and Learning with Music Technology developed on WebCT. Results of the students' assessment are then presented with their main concerns about the environment. Then, the redesign of the whole content is discussed. The students' assessment of this modified content are then presented.

Introduction

"WebCT (short for Web Course Tools) is an integrated set of tools for developing and delivering interactive course or course components over the Web" (Friesen, 2000, p.3). This tool is the one prescribed for the whole University Laval. Note that, before retaining it, members of a committee, from which the author was a member, first tried several platforms during the academic year 1999-2000. The next year 2000-2001 was characterized by a WebCT pilot project implying professors giving courses in various disciplines. The author was one of them. The course was the undergraduate course MUS-19673 Teaching and Learning with Music Technology, a mandatory one for the program of Bachelor in Music Education and an optional one for the others undergraduate programs of the Faculty of Music. The lack of equipments available to the students forced the professor to use WebCT to deliver course components instead of developing a fully interactive course. There were 30 students using this release of the course.

The components of the first year of use

As the author was aware that the adding of a Web tool does not mean any enhancement of the course because, as mentioned by Heines (2000), "... the determination of what really works is so difficult", she used what we will call several "content prescriptions" found in the literature (such as Anderson, Tolmie et al.,1993; Chen and Rada, 1996; Cherry, Fisher et al., 1989; Dwyer and Baker, 2000; Friesen, 2000; Mohageg, 1992; Williams and Webster, 1999; Wright and Lickorish, 1994). She also integrated what was said as being "obviously helpful even if not empirical evidence found" during the so numerous sessions and workshops she was enrolled to.

When designing the content, we took care at several criterias mentioned in the literature such as:

- The courseware provides information that accurately represents the topic.
- The courseware screen layout is easy to understand.

- The courseware content is presented clearly.
- The text information is presented clearly.
- The pictorial information is presented clearly.
- The graphical information is presented clearly.

The icons used in the main window are not the ones provided within WebCT. This design choice was assessed by the student as being a very important one. Because the professor was repeatedly said that it was a "must" to put the learning materials on WebCT, such as the different parts of the course notes, the content of the Powerpoint presentations made during each classroom meeting, the course plan the description of the exercises to perform, etc., it was done. Students found it was not convenient to have to download them and then, to have to print this teaching and learning material; moreover, they did not want to be forced to load on WebCT to have an access to this material.

Students found very useful the presentation of the topics that will be done during each meeting with the group (3 hours a week during 15 weeks = 3 credits course at Universite Laval). An example is presented at Figure 3. They did not like the "book-like" table of contents presentation though.

Lessons learned from the assessment of the first year release

As said above, we learned that students absolutely don't like to be forced to use WebCT to get access to the learning materials. On the other side, they suggested us to put several banks of examples that would complement, in a dynamic way, several aspects of the course content (for example, the principles of interface design or evaluation of a CAI tool in music). Students wanted that many examples and counterexamples of the applications for music teaching of a design principle be available. In the same way, they wanted that several examples and counterexamples of analogies that can be used to help a student to understand a particular musical language concept be presented. They also mentioned that visual synthesis of the information contained in a section would be very useful.

Students mentioned that the use of Mnemonic words would have helped them to actually become comfortable with the navigation within WebCT. So, instead of using a wordy table of contents, they would have prefer the use of Mnemonic words aiming at helping to make the link with the more formal course notebook and the presentation and activities performed during the classroom meetings (both assessed as being the heart component).

Students insisted to ask for real examples, i.e., real existing softwares, existing interfaces, real bad combinations of colors or good combinations of colors, etc.). Regarding when they prefer to have access to any WebCT content, most preferred to be able to have a look on the examples, simulations, etc., before the classroom meeting. The quizz section was totally suppressed and replaced by a forum of exchange of findings made by the students on a topic or another.

To summarize what we learned after this first year, we found that students would prefer that WebCT be used as a complementary tool and mostly to present what can't be effectively presented on paper. Because of that, we thrown away large parts of the site and began a complete redesign of the whole thing.

Implementation of Java Applet Solution for e-Learning in Physics

S. Boutiche
Dpt. of Physics, University of Bechar
08000 – Bechar, Algeria
e_learning_1@hotmail.com

Abstract: Developing courses in physics for conventional learning is a task variably complex, which consists generally in gathering and putting in a predefined pedagogic order a set of data (lectures, papers, courses,...) susceptible to be presented either directly/orally (classroom, conference, ...) or indirectly (book, article in a review, ...). In parallel to the course presentation, an experimental work/description -if available- is quite indicated to support the theory on which the study is rested.

The process to be followed to develop ecourses (or more generally eresources) for e-learning in physics is somewhat more complex since it requires -in addition to the above pedagogical considerations- a software solution designed for the accessibility mode (local PC, intranet, internet, ...) and adapted to the pedagogical goals to reach.

It is the purpose of this communication to present a java applet solution as a model for an e-learning course in physics via the internet and to show its high performances compared to conventional learning solution.

Introduction

Up to now, it is not easy to find in the specialized media of e-learning a consensual definition of what e-learning is and the problem becomes more acute if it is question to search a standard definition of e-learning in fields as varied as commercial sciences, medicine or physics. This is certainly due to the fact that elearning is an emerging science which is not yet fully integrated into our "conventional" systems of education. At the moment each elearning solution is a response to specific needs defined by the pedagogic goals of the studied subject within the physical limits of the elearning solution provider. In this context, it is the purpose of this communication to present in the following a model of an e-learning solution for higher education in physics implemented with the help of java applet solution (graphic interface of java language program).

Implementation of java solution for physics courses

The study of any subject in physics consists often in solving equations to obtain solutions susceptible to give information about the evolution of the studied system. Solving for example some equations of the fundamental principle of dynamics for a particle yields information about its position in space, its velocity, its acceleration and many other parameters. By integrating these data in a software solution, it becomes possible to simulate the exact motion of such a particle/system. If in addition our software solution is object oriented as is the case of java applet technology (of Sun Microsystems) the solution becomes "visual" and any parameter can be represented graphically.

On the other hand, it is easy to admit for the pedagogic output that a graphic representation carries more information when it is animated than when it is not. Then the possibility to simulate a visual motion in real time is of capital importance since it confers our elearning solution the possibility to be in the same time a course with a high level of pedagogic performances and a reliable e-device for an experimental work.

To illustrate this let us compare briefly our java applet (e-device) with a real device when the simple pendulum motion is studied.

Pedagogic comparison

In the classic device, the physical parameters or mathematical objects (such as the thread stress, acceleration vector,...) are not "visible" and are accessible to our perception only through equations. With the help of our e-device or e-pendulum not only such objects can be easily represented but their evolution in real time can be shown. With such e-device, the teacher task is certainly less laborious and the student more receptive to the studied subject.

Economic comparison

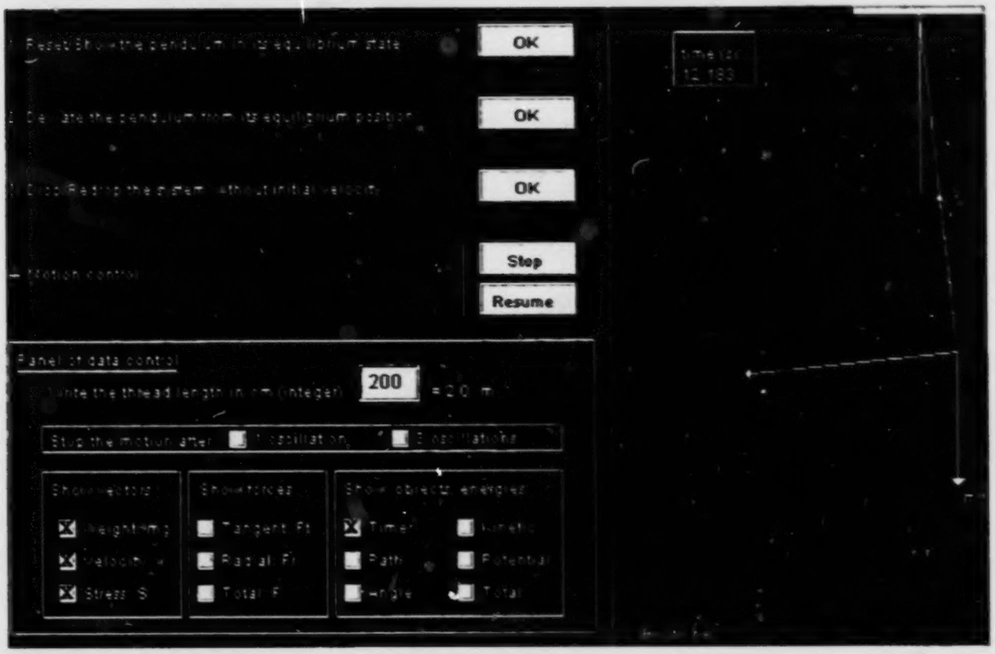
The cost of our e-device, is certainly lower than the cost of the conventional device for at least two reasons:

-The production cost of an e-device is lower

-The consumption cost of an e-device is also lower

Example

The java applet is an object with which it is possible to interact and the number of the offered functionalities is determinant for the e-learning solution quality. To have a maximum of functionalities, I have divided in two equal parts the applet surface: the left side of the applet (Image 1) constitutes the command panel which contains buttons, checkboxes, ..and in the right side of the applet one can observe the evolution of studied system. All applets that I have designed are constructed upon this model. I show in the image bellow, how a command panel is designed and the main interactive actions are sequenced: 1, 2, 3,..When the 3rd button is clicked, the e-pendulum starts its motion. It is possible to vary the thread length by writing the needed length in the corresponding field. If checkboxes are checked, the corresponding objects are shown (see checked boxes in Image 1).



Reset:Show the pendulum in its equilibrium state
OK
Deviate the pendulum from its equilibrium position
OK
Drop/Release the system without initial velocity
OK
Motion control
Stop
Resume
Panel of data control
Write the thread length in cm (integer)
200
= 2.0 m
Stop the motion after
1 oscillation
3 oscillations
Show vectors
☒ Weight
☒ Velocity
☒ Stress S
Show forces
☐ Tangent Ft
☐ Radial Fr
☐ Total F
Show objects, energies
☒ Time
☐ Path
☐ Angle
☐ Kinetic
☐ Potential
☐ Total

Image 1: Command Panel (left) with screen of observation (right) of java-pendulum

Conclusion

Java e-learning solutions are characterized by two fundamental elements: low cost of production and consumption with a high pedagogic output. Consequently it is not difficult to predict for the near term that the java solution will take a prominent place in any educational system.

Instructional Design for E-Learning

Switching Sides of the Desk:
Two Instructional Designers Discuss Their Teaching Experiences

Introduction and Background

Mary Lynn Brannon and Barbara Brazon worked together in the Penn State University system as Instructional Designers at different campus locations. Their primary role was to work with faculty to incorporate new technologies and pedagogical approaches. They had worked with and advised faculty on such areas as collaborative learning, use of Internet technologies, groupware, and the team building process.

Barb Brazon is now a faculty member in the newly formed School of Information Sciences and Technology. Mary Lynn Brannon has continued in the Instructional Design position but has also taught in the Human Development program.

Ms. Brazon had prior teaching experience but the teaching role was new for Ms. Brannon. Moving from the design phase to the implementation phase brought the process full circle and helped us to better understand some of the faculty challenges.

Teaching Technology Skills in a Human Services Course

HDFS 302 – Leadership and Technology Skills for Human Services Professionals

HDFS 302 is designed to develop skills and competencies in communication, collaboration, team building, problem-solving, critical thinking, empirical inquiry, technology/information data management and leadership. To develop these skills and competencies students participate in assignments that require students to work in teams live and at a distance via electronic communication to accomplish goals and objectives. The assignments are built around content areas utilizing role play, cased-based learning and presentations focusing on topics from the human services field. Students select local agencies to interview and present to the class on these agencies. Students are required to use technology tools in all their assignments. Each assignment focuses on a tool, such as MS Word, PowerPoint, Excel, and Front Page. Students are also required to use the web for research and properly cite print and electronic sources; and evaluate web sites.

Mary Lynn Brannon team taught this course in Fall and Spring 2001-02 semesters. She was the technology expert and her colleague, a domestic violence counselor, was the content expert. Together they developed assignments that coupled the content area of human services with technology. A case was written that required students to utilize the technology, communication skills and research skills. The students, working in groups, presented on a local human services agency. The project had to incorporate use of Excel, PowerPoint, interviewing skills, and a group portfolio with an individual research paper from each students and examples of web research. The students completed the course by designing and publishing a professional/personal web page.

Hybrid Learning in the IST Curriculum

Background on the Information Sciences and Technology Degree Program

In May 1998, an Information Sciences and Technology Strategic Planning Group recommended that Penn State University should create a School of Information Sciences and Technology (IST). In March 1999, the University Faculty Senate approved curricula for both baccalaureate and associate degree programs. Forty-three new courses were approved.

Since the initial offerings in Fall 1999, the School of Information Sciences and Technology has focused on developing a strong interdisciplinary foundation for the major. The undergraduate IST curricula are common across the nineteen Penn State campus locations. A total of 2200 students have enrolled statewide in the forty nine courses now offered in the degree programs. The first baccalaureate degrees were conferred in May 2002.

Meetings are held with the school's faculty and administrators fromall campus locations offering IST programs three times a year. Course development efforts have been a key ingredient for these meetings. The rapid growth and deployment of the program has also been aided through the Solutions Institute. The Solutions Institute was formed to enable quality and consistency. Four online courses are currently being delivered (IST 110, 210, 220 and 250). The courses have been designed with a modular, problem-based approach so that each can be offered wholly online or by using elements in a face-to- face fashion.

IST 210 – Data Organization – Barb Brazon

The online version of IST 210 was designed to be used as a hybrid model that supplements the faculty experience and resources with online materials. This course approach examines not only the construction of a database using a programming language, but the implementation and utilization of Management Data Software. The course has a theoretical component that examines the database tools, and the implications of data security and public issues surrounding maintaining and disseminating information from a database.

During the Spring 2002 semester, Barbara Brazon taught this course in a hybrid fashion using both the online materials and a textbook. The course was conducted in face-to-face meetings throughout the semester along with weekly lab sessions; this was done to familiarize the students to the course tools, to develop teams, and determine competency and mastery of course material. After these meetings, the students worked both independently and on team projects. Students worked through assigned labs and read through the course materials online and in the book. Subsequent meetings throughout the semester were to review and to conduct demonstrations of material and concepts presented online or in the book. A variety of assignments allowed for team and individual assessment, as well as individual and group testing.

Lessons Learned

As instructional designers we advised faculty about the types of strategies available to incorporate into their teaching styles. As instructors in the classroom we were able to experience first hand how these strategies could be implemented with varying degrees of success.

The areas that we found particularly challenging were:

- Group dynamics
- Student motivation to work actively and independently
- Evaluation of team process
- Assessment of team projects
- ESL student writing assignments
- Different levels of technology skills
- Assessment of teaching effectiveness

We have looked at the faculty role through the Instructional Designer's eyes and it has helped us to greater understand the demands from the faculty perspective. It has also proved to be both exciting and humbling and we would recommend this experience for anyone in a faculty support role.

A Real-Life Paradigm Example of Designing and Delivering a Successful Hands-on Online Learning Experience for Members of a University Task Force on Technology-Assisted Education

Dr. A.-M. Brinsmead and Ms. Joan Gordon, CE, University of Toronto

Focus

The focus of the online learning experiences via web browsers on laptop computers in Task Force on Technology Assisted Education members' U of Toronto's offices for one hour on each of two consecutive days was to provide first-hand, high quality experiences in synchronous learning (in real time) and asynchronous learning (not in real time) within two of the School's existing online courses, **Advanced Professional Translation & Spanish for Professionals** and **Great Masters of Art** To this end, under the direction of Director Dr. Mary Barrie, University of Toronto's School of Continuing Studies used two Internet-based educational tools that were "best-in-kind" due to their flexibility in being able to deliver effective pedagogy, educator-learner interaction and academic administration.

Goals

- Provide hands-on experiences to Task Force members of real online learning experiences using some of the best instructional media in distance teaching in courses offered at the University's Continuing Studies' division. (A number of Task Force members had no previous online learning experiences.)
- Offer two high quality approaches to Internet delivery of optimal learning experiences in order to assist Task Force members in developing a framework within which to answer the questions raised by the university's future involvement in distance education: -Should U of T offer both credit and non-credit courses by distance education? –Should U of T develop and deliver its own courses? -What services are required – instructional designers, IT experts, etc.–– to support faculty in the use of instructional distance media?

Methods

A team of "mentors" comprised of the academic management staff from the School of Continuing Studies, coordinated by the head of the division, Dr. Mary Barrie, CFO and educator John Rawle, and ourselves (the authors of this paper), assisted Task Force members on laptops in their respective offices throughout the 1-hour online learning experience presentations. In addition to creating the instructional design and authoring and administrating the two online continuing education courses to be experienced by Task Force members, we co-delivered the presentations in fulfilling the roles of online educator and online senior administrator. In **the Advanced Professional Translation & Spanish for Professionals'** course, Anne-Marie moderated -- in the real time Chat environment in Prometheus-- a discussion on language and cultural etiquette for English speakers travelling abroad. In the Great Masters of Art course, Anne-Marie delivered --in real time-- a 5-minute lecture on Rembrandt and Monet by means of two-way audio- and video- communication in Centra Symposium, with a Q & A follow-up in real-time via text and audio chat amongst Task Force members regarding the value of the learning experiences and the questions they raised.

Results

The response to the online learning experiences' presentations were decidedly positive. The participants were impressed with how well-organized and thoroughly interactive and engaging these online learning experiences' presentations were, and with a modicum of technical difficulties. One participant said that this was the smoothest presentation of an online learning experience he had seen since he joined the U of Toronto in 1994. All participants were enthused by the "anywhere, anytime" delivery of substantial learning content materials on the wireless, "Personal Assistant" Palm Pilots. Participants preferred the asynchronous online learning environment over that of the synchronous audio chat environment because with the latter "we're not there yet", as participants articulated, in terms of synchronous, real time, TV-like quality of video- and audio- conferencing for delivering lectures and participating in discussions in real time. One reason for this is that Internet 2 bandwidth, which is not yet universally available, is required in order to receive TV-like quality of two-way video- and audio-conferencing. Participants found that, in particular, the learning experiences that they enjoyed in the asynchronous online learning environment had given them a comprehensive perspective on how teaching online with a virtual classroom approach --both "in real time" with live text chats and "not in real time" with the other features within the asynchronous online environment-- would be compatible and of comparable quality standards to those of U of T faculty's teaching as it is currently conducted in the in-class environment. High educator-student interactivity online was seen as a critical component of any technology-assisted education originating from the U of T. Many communicated that they believed that now they were better informed to make some of the Task Force on Technology-Assisted Education's decisions that were before them.

Summary

The Director of Continuing Studies summed up the results of this initiative by saying that this project, undertaken by Continuing Education on behalf of the university, one of the university's divisions at the forefront of online and distance education delivery with its programs in Business, Professional & Entrepreneurial Studies' certifications, its Professional Translation online certifications, and its web-enhancements of in-class Arts & Humanities programs, has provided a service to the university that is not insignificant and that is useful in practical terms. In Joan's role of Administrative Project Manager for and Anne-Marie's role as Educator in the Task Force members' experiences, we concluded that the university's senior management Task Force members were able to begin to grasp a more comprehensive understanding of what it means to learn optimally online for the adult learner. In coordinating a team of eighteen comprised of: mentors to the Task Force members, IT experts, and administrative staff providing back-up support at the School's "Command Central" before, during and after the presentations, we learned that in such a online learning experience project, you leave no eventualities to chance but have contingencies for all aspects of the experience being provided. For any university providing to senior university management online learning experience demonstrations such as this one, it is important to make ensure that the desired outcomes are informed decisions regarding asynchronous and synchronous software applications and acquiring university-wide competency in using such applications for online instructional design as well as effective and satisfying online teaching and learning, and to leverage human resources and activities in support of future university policies with regard to technology-assisted education. It is our view that, with our Continuing Education division's having delivered two sound and technically error-free "hands-on" learning experiences online to university senior managers, the university is now better equipped to steward its investment in Technology-Assisted Education.

The Impact of an E-Learning Environment on Students' Self and Peer Assessment.

Herman Callaert*, Saskia Litière*, Monique Maelstaf‡
Center for Statistics*
Office for Educational Services‡
Transnationale Universiteit Limburg
Belgium
herman.callaert@luc.ac.be

Abstract: This case study shares the experience of a first time introduction of an e-learning environment into an existing university curriculum. Students in biomedical sciences could choose, at the end of their third year of university study, among several elective courses. One of them was a course on effective communication, taught in the bioinformatics / biostatistics module. Classical contact hours in this course were drastically reduced through the use of an e-learning environment. The first exposure of on campus students to such an environment led to some noteworthy observations. For collaborative work, students made only minimal use of an electronic discussion forum, and preferred physical attendance in sessions organized by themselves. On the other hand, reflection on their own performance, as well as self and peer assessment, were substantially facilitated through the use of an electronic portfolio. Confidentiality, immediate feedback, and permanent accessibility may have played a key role.

Introduction

This paper reports on work in progress and wants to share experiences with similar experiments carried out elsewhere. The instructional innovation was carried out in an elective course. Hence participating students formed a self-selected group, and no control group was available at the time of the study. Any indication of possible interesting findings should therefore be substantiated by further investigation.

The change in students' attitude should be related to their cultural background as well as to the instructional and technological innovation. Most students at our university feel that they are personally responsible for their study results, and they translate this into "working hard on their own". They are not used to interrupt the instructor, they are shy at asking questions in public, and they rarely engage spontaneously in lively classroom discussions. Their preference for particular electronic communication methods is almost surely influenced by this cultural and educational background.

The physical environment plays an important role too. This study is about young full-time students, age 20, living and working on campus during the week, and going home every weekend (distances in Belgium are small). Moments of physical contact for discussion and group work can quite easily be organized.

Important also is the structure of the course, which is taught in an "all exclusive" system, where the academic year is divided into blocks of approximately 5 weeks. During such a block, only one "course" is taught, and students are expected to work full-time on it. Such a course can have different forms, and often runs as a multidisciplinary project. In the present study, the course on "effective communication" is a capstone course in the bioinformatics / biostatistics module.

Methods

The instructional innovation included cooperative learning. For some tasks, groups were assigned by the instructor. At other occasions, students were asked to work in groups, but were free to choose the size and the composition of the groups. They were also asked to report on their decision process in such situations.

The technological innovation included the introduction of Blackboard as an e-learning environment. It was mainly used as a means of communication at different levels. It contained practical information about staff and office hours, a calendar, a detailed description of the objectives of the course, the assignments with due dates, and additional course documents.

Apart from the email facility, a structured discussion board was set up, with a forum for each main topic of the course. Also electronic groups were created. They often reflected the actual composition of the groups in which students were working together. But there was also a "personal e-group", having as members only the particular student, the instructor (a senior statistician), and a senior colleague in educational psychology. The T.A., who was a younger person in the same age range as the students, had no access to this personal e-group.

Results

Students had to write reports and give presentations on professional topics like the use of decision trees in screening for breast cancer, the meaning of p-values, the design and analysis of clinical trials, etc... They organized themselves for working in subgroups, decided on place and time for meetings, and tried to divide the workload evenly among each other. During this whole process, students preferred face-to-face contact rather than the use of an electronic discussion forum.

Students were also asked to reflect on their own study strategy and on the dynamics of the group process. They had to write this down in a journal, placed in their personal e-group. This e-journal writing has played a major role in their learning process, in their evolution in self and peer assessment, and in the feedback for the instructor towards course design. The introduction of "impersonal" technology (e-journal writing) seems to have created a non-threatening environment for non-talkative and rather shy students. The direct and open style of the reflection about their own performance and about the group process was often amazing. Similar results have been observed in other experiments (Chance 1997). The e-journal writing also helped students to get aware of the evolution in their personal learning process, as they gradually linked their performance more and more to the set of objectives of the course. At the same time they also started using a checklist (provided by the educational psychologist) concerning emotional factors, such as social skills, assertiveness, and empathy. The reflection on their own performance, which started as an activity to promote reflective learning, helped to develop self evaluation skills, making students able to more accurately judge the effectiveness of their own strategies (leading to better products too).

The e-environment was supplemented by regular classroom contacts, with direct self and peer assessment of the reports and the presentations. At the beginning students were very reluctant about peer assessment and refused "to score each other". Formative assessment however seemed feasible and it didn't take long before the need for precise and objective criteria arose. Students then were asked to agree as a group on a set of self-chosen criteria to be used for further peer assessment. This strategy worked quite well, peer assessment became less threatening, and students made serious progress along the way. The ongoing reflection on the whole process, as written down in their e-journal, might have played an important role too. Receiving real-time feedback (Lovett & Greenhouse 2000) but also giving real-time feedback on other students' work might make learning more efficient. Learning how to do this can be stimulated through simultaneous use of face-to-face interaction and e-journal writing.

Revitalizing Native American Cultures through Virtual Museum Projects

The richness of American Indian culture is widely recognized and of great interest to Native and non-Native people alike. Many cultural and historical artifacts of Native life are spread across the collections of museums and private holdings. Such holdings may be viewed on site or, increasing, electronically through virtual museums. Still, many tribal members have limited access to their own cultural heritage and may be excluded also from interpreting these objects even when publicly displayed.

Native people today are a modern people, but many are alarmed at the loss of the traditional ways and the Native languages that connect them to their ancestors. As the oral tradition falters in an age of mass media, Native elders wish to have some record made of their knowledge. At the same time, there are sacred aspects to Native traditions that should not be shared with others outside their communities. Native people have also been afflicted by the appropriation of their cultural practices by non-Natives, a violation of cultural property rights that is much like the violation of intellectual property rights. Today Native Americans are seeking ways to counter these trends and to revitalize their cultures as they enter the twenty-first century.

As part of the self-determination efforts by American Indian tribes in the last half of the twentieth century, many institutions have evolved that help to address the critical issues for cultural revitalization. Tribally controlled schools and colleges have been created to improve the academic achievement of Native Americans by teaching in culturally relevant ways that value and validate traditional Native knowledge. Tribal schools have culture programs designed and taught by Native people that explicitly teach tribal history and traditional languages, lore, and arts. Tribal museums and archives have been created to maintain and display collections that tribes have acquired within their communities and from repatriation efforts. Tribal museums have also been involved in efforts to increase access to their collections through virtual museums. Tribal culture centers are institutions that develop a variety of programs that bring community members together to share and celebrate in traditional ways.

The Smithsonian National Museum of the American Indian (NMAI) has one of the largest collections of Native American artifacts in the world. It cares for over a million items for the public, but primarily for Native Americans. The NMAI seeks to find ways to serve its Native and non-Native clientele as it attends to the issues of access to cultural items, a revitalization of traditional knowledge and Native languages, and the appropriate use of cultural property.

The Four Directions project was a six-year education project funded by a U.S. Department of Education Challenge Grant (see http://www.4directions.org/). Its goal was to develop technology-supported curriculum and learning projects for culturally responsive teaching. The project partners included nineteen tribally controlled K-12 American Indian schools, four universities, and two museums. Even though financial support for the Four Directions project ended in September 2001, many of the project partners have been working to continue its goals. The University of Texas at Austin and the Smithsonian National Museum of the American Indian were two of the Four Directions partners that are still seeking ways to work together to continue the Four Directions mission.

In 1999, the Four Directions project began to develop its first virtual museum project in partnership with the National Museum of the American Indian. Another Four Directions partner, the University of Texas at Austin, took a leadership role in the planning and implementation of the virtual museum project. Over a two-year period, three of the Four Directions schools sent teams of students, teachers, and community members to develop a Virtual Tour of the National Museum of the American Indian (see http://www.conexus.si.edu/VRTour). In order to give the most immersive virtual museum experience that was feasible from a K-12 project, the virtual tour made extensive use of QuickTime Virtual Reality media to show the museum environment and the objects on display. The Native American students researched the items of the exhibit with the help of community members, teachers, museum staff. They then wrote the essays that accompanied their virtual exhibits, giving the Native American voice to the virtual tour.

From the NMAI Virtual Tour experience, a Four Directions model of virtual museum projects evolved. The model conceptualizes virtual museum projects as partnerships between Native American schools and museums that operate within three overlapping and interacting activities: cultural responsive teaching, cultural revitalization, and cultural collaboration:

- ***Culturally Responsive Teaching*** — Virtual museum projects are culturally responsive because they teach through the culture of the child to bring community concerns and values to the center of the teaching-learning process. Students are motivated to excel because they are doing important, original work to recover and preserve their heritage. They gain from the knowledge of museum professionals and the wisdom of community elders. They develop skills in research, writing, social studies, science, mathematics, information literacy, and cutting-edge information technology.

- ***Cultural Revitalization*** — A common concern among Native American peoples is the recovery and preservation of their cultures and languages. Much of what remains of traditional material cultures resides in museum collections far from Native American communities. Virtual museum projects provide a way for communities to "digitally repatriate" precious items of cultural heritage. In the Four Directions Model, virtual museum activities also take place in the Native American communities. Students research and record local materials that supplement the museum's resources for the virtual museum. Local resources such as oral histories, cherished heirlooms, traditional stories, dances and songs, native language and contemporary arts get combined with museum materials to present the vision of a vital, living culture.
- ***Cultural Collaboration*** — Although museums aim to preserve heritage and educate the public, Native Americans sometimes object to the way museum exhibitions appropriate cultural property. Native Americans often want the public to have access to authentic knowledge of their histories and cultures, but they also believe that some aspects of their cultures should not be shared with outsiders. Virtual museum collaborations can provide a venue to address thorny issues of cultural property rights, to design protocols for cultural collaboration and to decide levels of access.

In the last two years of the Four Direction project, nine virtual museum projects were conducted with eleven of the Four Directions schools in partnership with ten museums. The Four Directions Model for virtual museum projects could not be applied completely in some of these projects, but it became a valuable standard that guided their design.

The National Museum of the American Indian has begun to apply the lessons learned from its experience with the Four Directions project to its own program. In August, 2001, the NMAI brought a team of students and community members from Pine Ridge Reservation to create a virtual exhibition of Lakota history and culture for use in the Little Wound Tribal School culture program. In addition to using QuickTime VR media and still images, the Little Wound participants also created audio commentary in English and Lakota language for the virtual exhibition. The NMAI has plans to conduct similar programs with tribal schools, colleges, museums and culture centers several times a year.

To continue its partnership with the National Museum of the American Indian, the University of Texas is now seeking funding to continue its involvement with Native American virtual museum projects as a way of revitalizing Native cultures. These projects will refine and extend the Four Directions model.

The poster session will provide a display and handouts on the past and current efforts in virtual museum projects that have been conducted by the National Museum of the American Indian, the University of Texas and the Four Directions project. Samples of the virtual museums will be accessible on laptop computers for conference goers to experience.

The poster session presenters will include **Mark Christal**, a graduate researcher on the Four Directions project and a doctoral candidate at the University of Texas; **Paul Resta**, professor in the Instructional Technology program and director of the Learning Technology Center at the University of Texas and Principal Investigator for the Four Directions project; **Loriene Roy**, professor in the Graduate School of Library Information Science at the University of Texas and Four Directions partner; and **Marty Kreipe de Montaño**, manager of the Cultural Resource Centers of the Smithsonian National Museum of the American Indian and Four Directions partner.

Light Bridge: Employing Internet2 in Support of Pre-Service Teacher Education

Brett Christie, Ph.D.
James Fouché, Ph.D.
School of Education
Sonoma State University
United States of America
LightBridge@sonoma.edu

Abstract: Though bandwidth size continues to increase significantly, there are few projects or resources that fully capitalize upon the potential. High-bandwidth-enabled uses of technology can enhance teacher education and create more engaging learning in K-12 classrooms. A challenge facing California is that there is very little content that has been developed specifically to utilize Internet2 for teacher education or learning in the K-12 classroom, despite the fact that substantial resources have been devoted to the Digital California Project for establishing a statewide, high-bandwidth network among schools, colleges, and universities. However, there are emerging programs that utilize this resource for its potential contribution to educational and professional development content. This paper discusses one example, *Light Bridge*, a project funded by the U.S. Department of Education program, Preparing Tomorrow's Teachers to Use Technology. Examples of *Light Bridge* endeavors include using digital video-based lessons in a web-based environment to help teacher educators better prepare pre-service teachers through more engaging and authentic means.

High-Bandwidth Augmentation of Teacher Education

Increased bandwidth is enabling increasingly innovative and exciting ways of using technology to enhance teacher education and create more powerful and engaging learning in K-12 classrooms. A challenge facing California is that there is very little content that has been developed specifically to utilize Internet2 for teacher education or learning in the K-12 classroom despite the fact that substantial resources have been devoted to the Digital California Project for establishing a statewide, high-bandwidth network among schools, colleges, and universities. However, there are now a small, yet growing, number of programs designed to utilize this resource for its potential contribution to educational and professional development content. One example is *Light Bridge* (www.sonoma.edu/lightbridge), a project funded by the U.S. Department of Education's program, Preparing Tomorrow's Teachers to Use Technology (PT^3). *Light Bridge* is one of 15 catalyst grants awarded by the USDE for 2001-2004. Examples of *Light Bridge* endeavors include using digital video-based lessons in a web environment to help teacher educators better prepare pre-service teachers through more engaging and authentic means. These resources are also appropriate for practicing teachers seeking examples of current and effective teaching techniques to add to their repertoire.

Light Bridge is a consortium led by the School of Education at Sonoma State University. The School of Education has 550 teacher education students annually and 90 full and part-time faculty. Specific goals of *Light Bridge* are to:

- Strengthen teacher education programs through the development of rich video content offered via the next generation of the Internet.
- Establish a student teacher support and supervision system that assures high quality support and assistance at a distance.
- Disseminate teacher education video content, online resources, and student teacher support and supervision system.

Specific examples of *Light Bridge* activities include developing and maintaining rich visual teacher education content; piloting the use of video conferencing for teaching, supervision, and mentoring of pre-service teachers;

and capturing the classroom performance of pre-service teachers for analysis and criticism by mentor teachers and university supervisors over the network.

In its formative stages, the *Light Bridge* site was developed with feedback gained from an extensive usability study. Sonoma State University students, faculty, and staff participated in usability tests that helped determine layout and design features and characteristics that were useful and desirable. In addition, these subjects also viewed video samples that were purposed toward web-based instruction on a particular topic. This also yielded helpful data in guiding *Light Bridge* content developers toward higher quality videos and lesson content for the web site.

Another important feature of *Light Bridge* is the extensive videography training for faculty content developers. Workshops totaling 30 hours were focused on videography in classroom environments. These workshops ranged in topics and skills from basic lighting and background, to the more complex issue of acquiring desirable audio. The latter proved to be the most critical and a challenge that had to be met head-on. We quickly determined that, without quality audio, there would be very little usefulness of the video or content in this format. In addition, all content developers participated in extensive iMovie training, led by an Apple representative. In addition to simply going through the steps of iMovie, content developers brought in footage they used for iMovie editing practice, which was then screened for peer-feedback. This proved extremely useful, as it made the workshops highly authentic -- each faculty member went through the learning process in a context that was specific to their project. After this series of workshop, we held subsequent meetings with the sole purpose of each content developer screening their latest work to the rest of the group. This proved to be effective for feedback and enhancement of the work being developed. An added effect is that it helped to keep the content developers' workflow moving forward toward our target completion dates.

The final issue to be addressed was how best to format and store the content and videos, and whether to use streaming or progressive download approaches. In addition to discussion with experts on campus, *Light Bridge* directors attended QuickTime Live in February 2002. QT Live was very useful for learning the latest in digital video development, editing, compression and decompression, and web streaming. As a result, we were able to finalize these specifications for our project and make arrangements for post-production and posting to the web. One key decision that was made was not to stream, but rather to use progressive download ("Fast Start"). This allows the videos to be played immediately. Also, if a user wants to save the video file, they are allowed to, as the videos and content are public domain.

Over the course of academic year 2001-2002, *Light Bridge* deliverables include: 15 web-based video and content lessons; 300 pre-service teachers taught in part through this method of instruction, and; 42 practicing student-teachers supported through videoconferencing as a means for interaction between the university supervisor, student-teacher, and resident teacher. Over the 2002-2003 academic year and beyond, these numbers are projected to reach approximately 60 web-based lessons, 2,800 pre-service teachers taught, and 150 student-teachers supported by videoconference meetings and supervision. An expanding network of collaboration and dissemination will accomplish this. Finally, a self-authoring tool for the web site will allow educators with an interest in developing such content to make submissions of video-based lessons for preliminary acceptance to the *Light Bridge* web environment. This content will be temporarily displayed on the *Light Bridge* web site in a section titled "The Screening Room." Content will then be peer-reviewed by a team of evaluators and feedback given to the author(s): To be accepted in its current state; To be slightly revised as requested, then resubmitted, or; Not acceptable or inappropriate to the project.

A unique and helpful feature of the *Light Bridge* web site is that the video and content lessons can be accessed by searching on a number of variables: topic; grade level; or standards. In addition to the California Standards for the Teaching Profession, *Light Bridge* supports implementation of the International Society for Technology in Education (ISTE) Standards for Teachers. *Light Bridge* lessons not only cover specific subject matter areas and topics, but also include the infusion of technology in various lessons. It is the goal that visitors to the site will be able to search by ISTE standard to find a lesson that demonstrates infusion of a particular technology and standard into teacher education. Through, *Light Bridge* we have started to fill the void of viable educational content to be delivered by California's Internet2.

Assessing the Processes of Online Teaching and Learning: A True Measure of Assessment

Patricia Comeaux
Professor
Department of Communication Studies
University of North Carolina-Wilmington
United States
comeauxp@uncwil.edu

Ele McKenna Byington,
Associate Professor
Department of English
University of North Carolina-Wilmington
United States
byingtone@uncwil.edu

Introduction and Analysis of Research Literature

We know, from our experience and from the research literature, that successful online teaching and learning involves computer-mediated communication processes and in which students and teachers are actively and reciprocally engaged in the process of knowledge construction, creating and sharing meaning, theory-based applications and situational problem solving. Although scholars use different terms—collaborative learning, problem-based learning, social constructivism, small group learning—they are essentially describing online teaching and learning as reciprocal processes in which knowledge is created and negotiated in a communal space by members of groups involved in authentic real-world situations. (Brandon & Hollingshead, 1999; Byington, 2002; Comeaux, 2002; Comeaux & Nixon, 2000; Hiltz, 1998; Hiltz et.al. 2000; Kloldner & Guzdial, 1996; Koschmann et. al. 1996; Moller, 1998; Romiszowski, 1997; Rovai, 200; Turoff, 1999).

Furthermore, this is the kind of learning and interaction that is known to be of value for the educated individual for the twenty-first century. As Dede (1996) asserts, "Educators must help all students become adept at distanced interaction, for skills of information gathering from remote sources and of collaboration with dispersed team members are as central to the future American workplace as learning to perform structured tasks quickly was to the industrial revolution" (p. 30). And as Romiszowski (1997) so clearly articulates, "the employable adult of the future must develop the skills of thinking critically and reflectively. . . the known effective learning strategies for the development of such skills involve intensive interaction [through computer-mediated conversations] not only with content structured into knowledge networks, but with other people (both 'masters' and other 'apprentices' who have an interest in the specific knowledge domain" (p. 34).

Thus, as educators we *must* critically assess the characteristics and the quality of these valued and known processes of online learning. In other words, we must develop assessment tools that will evaluate the processes of computer-mediated conversations in which students are actively engaged in thinking reflectively and critically as well as problem- solving with others of like-minded knowledge and interest. In essence, we must focus on process rather than outcome. This type of learning is best understood from the participant's viewpoint and as Koshmann (1996) articulates, "learning can best be understood 'as a distributed, ongoing social process, where evidence that learning is occurring or has occurred must be found in understanding the ways in which people collaboratively *do* learning and *do recognize* learning as having occurred" (p. 42, italics added).

Purpose of Poster Session

Therefore, the purpose of our poster session will be to present numerous assessment tools, which have been developed specifically to evaluate the processes of online learning. These tools have been developed and used by online instructors who adhere to the philosophy of learning described above. Examples of such tools include:

- Rubrics that assess the quality of computer-mediated communication (CMC)
- Online participant interviews designed to ascertain met and unmet expectations
- Online participant interviews designed to ascertain perceptions of course goals and objectives and of learning processes
- Tools for assessing the characteristics of instructional design conducive to critical and reflective thinking.
- Tools for assessing particular courses
- Tools for assessing student progress during the semester

KMi
Knowledge Management Interactive, Inc.
5025 Arlington Centre Blvd., Suite 240
Columbus, Ohio 43220

Phone: 614.326.6304
Email: info@kmionline.com

KMi provides comprehensive eLearning solutions for both corporations and higher education. From interactive learning modules and learning management system solutions, to a full range of planning, implementation and hosting services, we offer the support necessary to assure access to quality education and training.

eLMS – Learning Management System

KMi's eLearning architecture, **eLMS**, is a complete solution for flexible registration; content management and delivery; communications and user tracking.

- Web-Based User Management System
- Performance Tracking
- Assessment-Based
- Flexible Content Integration
- Database Driven
- Bandwidth Efficient

eLearning Content Development

KMi offers a variety of content presentation solutions to meet the specific needs of our clients.

- IPA - Integrated Playback Architecture (An online presentation format that incorporates audio, video, text and content slides.)
- eModules
- eCourses

KMi is experienced in developing learning environments that provide an outcomes-based, stimulating and interactive learning experience.

- Modularized Content Development and Delivery
- Integration of Assessment-Based Learning
- Video and Audio Supported Content
- Dynamic Multimedia Presentation of Materials
- Web-Based User Management System
- Content Language Translation Services

Technical Support Services

KMi offers a variety of support and helpdesk services. The KMi call center operates on extended business hours, five days a week. Service levels can be provided from administrator to end-user, and is managed by a trained support staff. Our technical support team has direct access to production servers, which means faster response times in addressing technical issues.

- 800 number support lines
- forms and email support services
- direct access to all necessary resources to address any issue

Hosting and Maintenance

KMi has developed a customer-centered solution that provides a robust, stable, and reliable environment backed by high industry standards in equipment and connectivity. Our service is supported by:

- Industry Standard Components
- OC12 fiber into front and back of building using 2 different network carriers
- Redundant Internet backbone connections over separate carriers
- DS3 connectivity
- Dedicated 100 megabit Ethernet switch port per customer
- 24/7 Network Operations Center with on-site personnel
- Climate Controlled Data Center
- Dual Diesel Generator Power Backup
- Fire Extinguishment System

KMi's Knowledge Base Components

Efficient and seamless sharing of best-practice information, curriculum and other assets is a vital ancillary benefit of KMi's eLMS. The eLMS Knowledge Base allows users to:

- categorize and share documents
    - by state
    - by author
    - by topic
    - by title
    - by date
- post information alerts and updates
- invite and schedule meetings between states
- manage collaborative events
- communicate directly via the site
- organize member contacts

The Knowledge Base and its related communication tools can be organized in user groups to determine who can view particular content. State administrators may hold rights to view all content, where learners may be limited in what they have access to view. All features can be set to prompt other users of new entries into the Knowledge Base via email.

KMi will provide this system **free of charge** when five or more states utilize the eLMS system.

Delivering video streamed library orientation on the Web: technology for the educational setting

by Karmen N. T. Crowther and Alan H. Wallace
University of Tennessee Libraries
Knoxville, Tennessee, USA

As college and university libraries prepare to meet the challenge of delivering quality services to an increasingly divergent 21st century population, traditional methodologies for providing those services also are changing. The development of the Web has greatly increased the electronic options that libraries now have available for service delivery. Despite the fact that libraries have been among the first on many campuses to use new Web-based technologies, one such technology, streaming media, has been little used. Yet it holds considerable promise for instruction and orientation, especially to the burgeoning number of remote library users on campus and in distance education programs.

We envision a number of library applications of video streaming. For example, one of our recent projects is a brief introduction to the UT Libraries that serves as a public relations tool. It shows prospective students, their parents, or anyone interested in the Libraries the facilities and services available to our users.

Video streaming may also be used successfully in library instruction, especially for multisection classes with similar assignments. We are currently working on an in-depth orientation for our freshman English classes at the University of Tennessee. These typically serve as venues for an introduction to the library, the catalog, and database searching techniques. Using video streamed presentations for such basic instruction will allow students to view the orientation day or night, whenever appropriate or convenient. In fact, any user new to the library or wanting a refresher could view such orientation. It has the added appeal of presentation in a medium that is familiar to and liked by students. To accompany these streamed tutorials we are developing online quizzes to be completed at the end of the instruction. This library orientation project is the primary work we will be sharing with others during the conference.

For the future we anticipate applications of video streaming to library instruction for upper-division and graduate students, even for faculty. By using a video streamed presentation for general orientation, one that could be viewed before a classroom session, class time could be spent on more specialized needs. Tutorials for especially challenging research materials could be created as video-streamed files. Any or all of these video-streamed applications would be useful in teaching distance education students how to do library research. Even in-house training for student assistants or library staff could be done effectively with video streaming.

As campuses turn increasingly to Web-based instruction, we consider video streaming to be yet another way that college and university libraries can be visible and accessible to our students and faculty wherever and whenever they need us.

Does Personality Type Effect Online versus In Class Course Satisfaction?

Richard Daughenbaugh, Ph.D. and Daniel Surry, Ed.D. and Mohammed Islam, MS IDD
BSET Department

Lynda Daughenbaugh, Ed.D
C & I Department

The study seeks to determine if different personality types express more or less satisfaction with courses delivered online versus those delivered in the classroom. This study employs two online surveys: the Kiersy Temperament Sorter(KTS) which sorts each respondent into a personality type based on 4 dimensions: Extrovert /Introvert; Sensing/Intuition; Thinking/Feeling, and; Judging/Perceiving, and a course satisfaction instrument (CSI) developed by the authors. Both the KTS and responses to the CIS will use descriptive and inferential statistics to determine if a correlation exists between personality type and course satisfaction. Subjects are college students in both online and in class courses. Conclusions drawn from this study will identify personality types which express satisfaction with online courses and to identify and modify areas of online courses that have low satisfaction ratings for different personality groups.

E-Learning for choral music ensembles: Evaluation of a contextual approach for enabling pre-service teachers to design and implement online learning experiences for choirs

James F. Daugherty
The University of Kansas

Survey data suggest that teachers lack sufficient preparation and background to incorporate substantive electronic learning into their teaching contexts. The Office of Technology Assessment of the U.S. Congress (1995a, 1995b), in one of its last reports, reveals that while over 50 per cent of teachers feel comfortable with traditional computer applications (e.g., word processing, tutorials, games, publishing), less than 10 per cent consider themselves competent to use more involved formats such as electronic network collaboration, problem solving applications, or multimedia. In a similar vein, the National Center for Educational Statistics (1999) reports that only 20 per cent of teachers feel prepared to integrate electronic learning into their classrooms.

Bosch and Cardinale (1993) find that many pre-service teachers have not experienced useful models that embody instructional use of computers in their undergraduate courses and field experiences. Baron and Golman (1994) indicate that pre-service teacher education tends to focus on less sophisticated computer skills that do not lend themselves to problem-solving applications or higher-order thinking skills. A recent study released by the Milken Exchange on Educational Technology (1999) finds that of 416 teacher preparation institutions surveyed, most report that technology use is not integrated into regular coursework or field experiences.

Benefits and dimensions of electronic learning for enhancing choral music rehearsals and choral music education courses have been identified and discussed by Daugherty (1999). Strategies associated with web-based rehearsal notes and links, web forms, electronic portfolio assessment, audio and video files, discussion boards, and electronic collaboration can relate "knowledge of" to "knowledge about" music making in creative ways that foster the active participation and reflection of each singer. Yet, students who, as learners, may favor such online engagement in their own education at the undergraduate level appear to have little clue how they, as teachers, might design such electronic learning opportunities for eventual use in their own classrooms and rehearsal contexts.

Methods and Procedures

This study extends an investigation by Daugherty and Daugherty (2000),which examined self-reported attitudes and abilities of pre-service teachers regarding the design and implementation of electronic learning opportunities for choral music ensembles. Over a period of three years, university students enrolled in a choral methods class , working toward certification as music teachers, participated in an electronic learning project as part of the course requirements. A particular focus of the project was to design electronic learning experiences in conjunction with the National Standards for Music Education and specific examples of choral literature suitable for school choral ensembles.

Specifically, the project sought to gauge the effectiveness of using models or templates that could readily be adapted for use with various real-life contexts and objectives. In other words, rather than teach technology per se, the project posed a problem: how to provide opportunity for choral singers to learn in a manner consistent with the National Standards for Music Education using choral literature the ensemble was then rehearsing. Pre-service teachers were invited to respond to the problem by brainstorming ways that technology could assist their instructional goals. Participants were also asked to dream of ideal learning opportunities, without concerning themselves with whether or not they had the technological skills to implement such opportunities in practice. Each of the three classes determined in this manner that synchronous rehearsal time should be spent for the most part in actual ensemble rehearsal of the literature, but that asynchronous electronic learning modules could enhance and make these rehearsals more efficient.

Six fifty-minute class periods were devoted to the project, including brainstorming ideas, constructing the modules, and sharing the finished products. The class met 45 times during the semester. The smartChoir project, then, encompassed 13.33 per cent of total class time. All participants learned to read and write very basic html in a synchronous class session. The purpose of such instruction was to enable them to know how to "steal" code and fix any common problems that may arise in the use of such mid-range WSIWYG software as BBEdit and Netscape 6. Thereafter, each participant learned how to implement such electronic learning components as web pages, basic html, hyperlinks, audio and video files, web forms, bulletin boards, etc., only he or she they needed them to further self-chosen instructional goals for a particular piece of choral literature.

Results

As indicated in Table 1, prior to this project the a majority of students described themselves as "totally lost" about how to design and implement electronic learning opportunities in a choral context. Interestingly, all students had previously had a one semester course in music technology required of all music majors. Following the project, however, a significant majority of students described themselves as "competent" (either "somewhat competent," "competent," or "very competent") to implement electronic learning in their teaching contexts.

Table 1

Participant Reponses Before the E-Learning Project

	Totally lost	Uncomfortable	Somewhat Competent	Competent	Very Competent
Respondents	22	14	6		
Percentage	52.38	33.33	14.29*		

*Compare to national estimates(OTA/NCES) of 10-20%

Participant Reponses After the E-Learning Project

	Totally lost	Uncomfortable	Somewhat Competent	Competent	Very Competent
Respondents	0	2	24	11	5
Percentage		4.76	57.14	26.19	11.91*

As Table 2 suggests, participants in this project responded favorably to the use of such a contextual approach for the design and implementation of electronic learning for choral ensembles and to their own intentions of incorporating such learning into the classes they would teach.

Table 2

Choral music teachers can learn to design and implement online instructional modules by following a pattern/model such as the one I used on my project:

	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
Respondents	0	1	1	22	18
Percentage	0	2.38	2.38	52.39	42.85

I will likely incorporate some form of online instruction into the choral music classes I teach.

	Strongly Disagree	Disagree	Neutral	Agree	Strongly Agree
Respondents	0	1	2	19	20
Percentage		2.38	4.76	45.24	47.62

Participants were also asked in a pre-test/post-test format to define in their own words the following terms: browser, server, ftp, hyperlink, html, .jpg, .wav, www. Whereas less than 10% of participants successfully defined all terms prior to the project, 100% defined the terms successfully following the project.

Discussion

Results will be discussed in terms of the feasibility of using a contextual approach to teaching teachers how to design electronic learning opportunities for music ensembles, and the use of templates to implement the web-based technology they wish to incorporate into such opportunities. Implications for teaching technology across the teacher preparation curriculum, rather than as an isolated technology course, will also be addressed.

HAMTUTOR: Author tool to develop adaptive multimedia courses

SUMMARY

An author system has been developed as a programming language of easy use, on the basis of a prescriptive instructed model with probed efficacy along the development process. This tool has been designed in such a way that users, without programming knowledge but experts in corresponding subjects, can use it and perform their adaptive multimedia courses and distribute them by distance educational systems.

Analysis of the prototype course developed using the adaptive multimedia author tool (HamTutor).

The author language HamTutor is a high level- programming system, i.e.: with both structure and significance close to human language. In our case, it must contain all required elements to allow the design of a distance educational course. In consequence, the developed tool allows, at least, the performance of e-learning courses with two navigation ways (Alcantud, F. & Tormo, M.J. 1997).

The e-learning-course user can be any Internet user. Navigation along Web pages or Internet can be carried out in either, free or guided way. HAMTUTOR enables the students to navigate along contents by these two navigation ways, according to their own choice (free way) and depending on their educational level (tutorial way).

Using the tutorial way, the student is limited to follow the instructions or advices given by a virtual tutor. In this form, the student only has to do that indicated by the tutor, at any moment. The only navigation options for the student are to go away or to go back along the different stages and concepts, to change the theme or lecture, to change to the free way, to see his evolution along the contents-tree and to exit (Romero C. 2002).

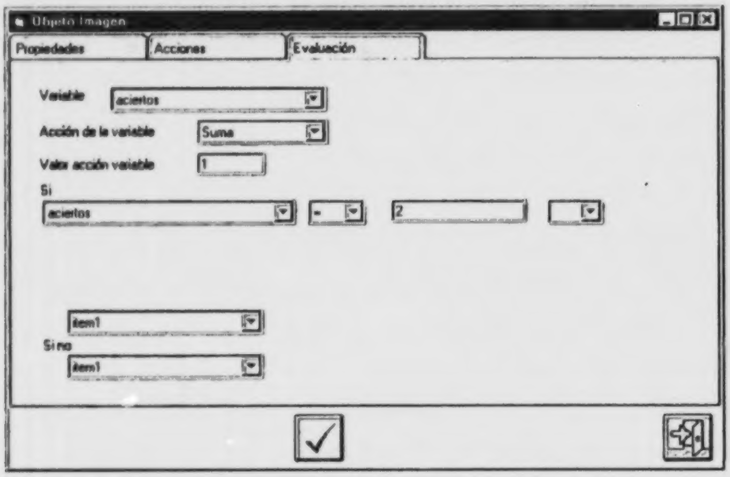
Concerning to the contents presentation, this tutorial way always gives an explanation of the subject and then, it proposes to carry out a Tutor-guided exercise.

The student of a HamTutor-developed, interactive multimedia course can navigate for himself along course contents and get the different tools and services given by the application. The possible options would be:

- To navigate along themes and lectures of the course in a free way, using an intelligent assistant from the tool-selection menu.
- To change of Section (Tutor, Practical, Summary, Glossary, Videos, Bibliography).
- To accede to different available tools and options (Notebook, Posit, Historian, Sound/Video Configuration, Intelligent tutor, Virtual world, Internet)

Evaluation system and navigation control

The information needed for the adaptive system to modify the learning sequence is obtained from a evaluation of the student knowledge level (Alcantud, F. 1997) . By using this information, we can break the sequence and transform our course in a non-lineal one. It is to say that, from the n concept we do not need to go to the n+1 concept. Depending on the knowledge level, we can encourage the student learning taking him to a x explaining concept before return to the n+1 concept, or we can go directly to the x+1 concept. In summary, it will allow the teacher to state the learning route for the student according to his competence level. With this objective, an evaluation system for the student competence has been designed so that the way through the different learning steps will be conditioned by such a valuation. To get it, a number of numeric variables are created in association to the evaluation items as above indicated in the example. Once these variables are made, each item is associated to an action so that the selected answer or the activity execution can modify the variable value and then, by means of a logical ratio, we can conduct the student to the desired item, concept, complementary lecture, etc. as is illustrated in the following example (Fig. 1):



Variable: aciertos
Acción de la variable: Suma
Valor acción variable: 1
Si: aciertos = 2
item1
Si no: item1

Fig. 1: Evaluation Interface

The Activating Learning Experience Supported by ICT

Toby De Loght
Prof. dr. Peter Van Petegem
Department of Education
University of Antwerp
Belgium
toby.deloght@ua.ac.be, peter.vantpetegem@ua.ac.be

Abstract: The starting point of this contribution is the concept of Powerful Learning. It contains 6 characteristics which we transformed into a structured model. The centre of the model consists of student-centered education and its accompanying coaching component. Surrounding the centre, there are three satellites: Content, problem-based learning and collaborative learning which are linked and in constant interaction with each other and the centre part. The improved concept was used in different teacher education programs at the University of Antwerp. Much attention goes to putting every component into practice and how ICT-supported course materials created value in shaping the curriculum within the boundaries of the concept.

Introduction

The approach of PLE has been applied in 3 courses from 2 different teacher education programs. One program is a professionalization course for teachers. The other program is a general teacher education program. These two groups are very diverse in motivation. The reasons why students attend the courses vary from learning to talk to a group of people, just getting an additional degree, learning new and interactive teaching methods, to becoming a good teacher in a secondary school. These differences show up in the way people study or the way they evaluated the course offerings. Depending on their personal course objectives, students tend to apply a different learning style.

A model for Powerful Learning Environments

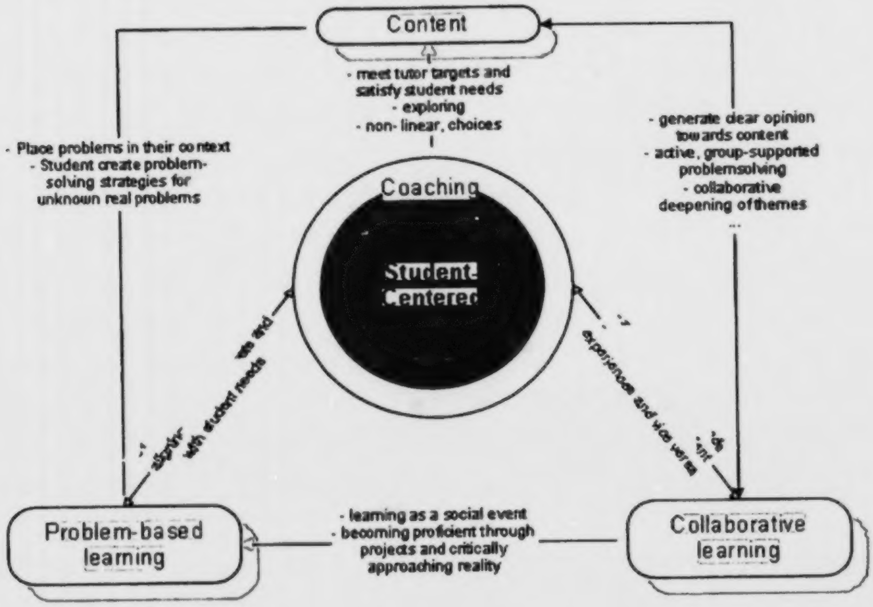
The concept of *Powerful Learning Environments* (PLE) by De Corte (1996) started from constructivist views on learning. Learning is basically characterized as a constructive, cumulative, self-controlled/self-directed, goal-oriented, context-bound and co-operative process. We transformed this basic set of characteristics in a working model to innovate the existing teacher education programs.

The depicted model (Fig. 1) sees different types of learning as a constant flow of interactions. Restructuring courses this way should attract as many different types of learners as possible, through activating them. Important to the whole story is the use of the basic competencies of Bloom's taxonomy (Anderson, 2001). We try to address all competencies and let them appear in different form, through coaching activities, simple content offering, problem-based learning, and ICT-supported collaborative learning, in order to make the courses as diversified as possible. (Brandt, 2002)

Student-centered

A teacher education program targets at acquiring the necessary skills, enabling students to perform well as future teachers. Putting students in the centre from the beginning makes them feel important and having responsibility. It eases giving coaching and guidance to students throughout the course. Student-centered working is a goal itself in this approach, since the purpose is to actively involve all students in learning activities and take advantage of their personal learning objectives and needs.

However, a student put in the centre thus becomes responsible for one's learning or even failure. A coach has to help people feel comfortable with the new way of working. Students have to stop absorbing factual knowledge and start constructing knowledge through exPLEration of resources.



Content
- meet tutor targets and satisfy student needs
- exploring
- non- linear, choices
- Place problems in their context
- Student create problem-solving strategies for unknown real problems
- generate clear opinion towards content
- active, group-supported problemsolving
- collaborative deepening of themes
...
Coaching
Student-Centered
with student needs
experiences and vice versa
Problem-based learning
- learning as a social event
- becoming proficient through projects and critically approaching reality
Collaborative learning

Web-learning: aspects of a new paradigm.

Orlando De Pietro, Francesco Appratto
Dipartimento di Economia e Statistica - University of Calabria
Via P.Bucci cubo 1C - 87036 Arcavacata di Rende (CS) - Italy
depietro@economia.unical.it
fappratto@economia.unical.it

Abstract: In this paper we discuss a new e-learning paradigm, the w-learning, which is based not only on the possibility of obtaining contents on demand, but it integrates traditional learning activities with web communities communication model. In the second part paper deals with w-learning technologies and, in particular, focuses on multi-tier web architectures, on XML and on metadata.

The support of ICT is becoming indispensable for conferring a high quality level in learning contents and a strong effectiveness in teacher's communication language; in particular Internet is becoming the primary way of communication among people, so e-learning and distance learning models are developing into a new and more complete paradigm that we can define web learning (w-learning) and that bases its communication structure and its services on the World Wide Web. Somebody considers the web a sort of "chaotic world" not only technologically but also about communication style, retaining fundamental to simplify user and communication interfaces and considering users of e-learning platform as consumers who have to obtain "products" (learning objects and contents) in an pre-ordered and rapid way. This way of projecting reveals great negative aspects: it deletes all free, inter-personal and interactive forms of communication which characterize Internet communities and it also defines a not flexible and hierarchical schema of relations among teachers and students. We can call this e-learning structure "hierarchical top-down paradigm"; the role of the latter is limited to contexts as company training or content on-demand by payment, where are very important: the precise definition of what user asks and the perfectly agreement between asking and answering; the rapid and effective accessing to contents; the possibility of requesting tutoring.

In high schools, colleges, universities and open collaborative working environments it's necessary changing from top-down model to w-learning, which is characterized by the presence of web-communities, with joint (peer-to-peer) collaborative forms of communication, and by the osmosis between learning environments and Internet. In this new kind of paradigm, users are Internet members and learning environment is a sub-domain of Internet, which can assume form of web-portal: Internet is then a new communicative paradigm applied to learning activities and the learning web portal isn't only a collector of services, but it's an immaterial place where it's hosted web-community life. The learning web portal has to support four primary communication forms: content and media on demand; synchronous multimedia broadcasting (for example using H.323); tutoring on-line, which is a synchronous and bi-directional activity between tutor and learner; collaborative and peer to peer communication among learning community's members, giving students permissions for uploading and sharing contents. It's evident that in top-down model the unique form of communication is asymmetric (one-to-one or one-to-many), whereas in w-learning, even if knowledge on demand has a primary role, all communicative paradigms present on Internet are collected and integrated into complementary (and not redundant) way. In this sense applying ICT to learning activity isn't only a way for helping remote users acquiring on-line all didactical material (resolving a lot of logistic problems), but it has two fundamental advantages: there is an increasing in didactical quality, because using an hypermedia language (audios, videos, texts, animations, etc.) there is a better meaningful clearness; students don't passively receive contents given by teacher, but they can value critically didactical material downloaded from web portal, by discussing with other community members (teacher, tutor, students).

Today there are available powerful cheap tools which can be used for multimedia broadcasting and multi-point web-conference: RealNetwork's RealSystem and Microsoft's Windows Media technologies have their plug-in in a great part of home computer, moreover there are other popular software tools that make easy representing learning object into various forms, using the simple textual media (see doc, pdf, html files) or using complex kind of animation movie (Flash and Shockwave animation, Java applet, etc.). In this case the problem isn't the possibility of representing contents in a multimedia form, but, paradoxically, the great variety of ways for doing it. The questions that instead we have to analyse and to resolve are: data creation, data storing and data presentation/selection. In w-learning paradigm their solution is more difficult because learner is very active and he doesn't limit himself to simply downloading files, but he researches, analyses and selects contents. If in the first phase of learning process it's better for students observing teacher's directives (in particular the teacher decides arguments order and their presentation bgic), in the second and final phase, instead, learner has to use researching and analysing tools for operating a critical synthesis of didactical material and for learning knowledge contained by it. W-learning platform must give tools for: designing ,teacher side, didactical contents; researching and analysing contents and data (using technologies for indexing learning objects); permitting collaboration activities and contents sharing between tutor and student or among w-community's members.

A web interfaced infrastructure for learning services can't be based on a single tier architecture where contents are statically defined, using a fixed form preventively chosen, and are presented to users without any dynamic elaboration. It's instead necessary adopting a multi-tier architecture characterized by dynamic management of business logic and presentation logic. In this way users' requests are analysed and elaborated just in time, so the answer can also refer to the last changes in the database where data are stored; moreover there is a higher level of flexibility and modular organization of elaboration process, distinguishing the storing domain from the business logic domain and from the presentation logic domain.

The principal multi-tier schemas can be implemented are: a dynamic processing of users' requests based on software modules (CGI, ASP, JSP or PHP pages) which receive HTTP requests, elaborate them and finally send HTML pages by HTTP responses; a data elaboration pipeline where contents are extracted from database, elaborated, translated into XML form and, in the last phase, there is the final translation into the form presented to user (for example by XSL binding).

It's clear that the second type of architecture is more modern because distinguishes semantic analysis of contents from the communication language used for presenting them to users. Another advantage is that XML data can be interpreted every time and everywhere because this language is software technology independent and data can be exported without having semantic problems; moreover XML permits easily implementation of multi-channel architecture, where there is the need of adapting output data to channel bandwidth and to terminal equipment used by user. In this case XML documents can be dynamically translated into a hypermedia and his complexity can de adapted to the specific transmission channel used: for example presentation logic modules can output a WML page, used in WAP mobile application, or a SMIL page, for complex hypermedia communication, or a simple HTML page; the most important things is that this doesn't influence data elaboration operated by preceding sections.

W-learning is characterized by the possibility given users of researching and analysing contents by powerful specific tools that point data stored into platform. In this case it's fundamental using indexing technologies and researching algorithm for extracting not only learning object but also part of them. For example we can obtain not only the link to teacher's lesson that is stored in the platform, but we can also request a link to a specific point of the lesson. For achieving this purpose, system developers need binding metadata to learning object, so that their semantic structure is clear, not subject to misunderstanding and unique. Scientific researching in this field is very active and has developed a great number of solutions (RDF, IEEE LOM, IMS): it may be useful choosing one metadata standard and using it. For obtaining a correct binding between data and metadata, teachers need specific tools, characterized by visual and friendly interface, which permit them creating learning object. In more complex case can be direct collaboration between the teacher and the technical team that works on presentation logic side. Particular difficulties can be found on indexing audio-video didactical material which is distributed on demand, asymmetrically and asynchronously: a possible solution can be developed creating a set of labels for each multimedia document; each label is a couple formed by a short textual legend, which shortly illustrates content, and by a little set of keywords, which defines the semantic context of the specific part. The SMIL can instead be used for multimedia synchronization; this language is moreover natively supported by some broadcasting server.

In this paper we have focused our attention on the basic and fundamental aspects of w-learning paradigm, explaining system architectures, technical features and new didactical methodologies. In particular we have stressed how ICT can give a strong effectiveness and clearness to teaching activity. For more details about our researching activity, the full text of the work and other news about the researching state can be required.

An On-Line Undergraduate Medical Genetics Laboratory

Miguel DeArce, Department of Genetics, Trinity College Dublin, Ireland, mdearce@tcd.ie

Teresa Logan-Phelan, Centre for Learning Technology, TCD, Dublin, Ireland, tlgnphln@tcd.ie

Ruaidhri Power, Department of Computer Science, TCD, Dublin, Ireland ruaidhri@netsoc.tcd.ie

Abstract Laboratories are the paradigm of scientific learning, where scientists 'discover' things. But often, such creative activity does not transfer well to the scholastic environment. Many standard ('wet') laboratory courses suffer from an intrinsic didactic deficit, as they seldom yield levels of learning or student satisfaction to match the investment. Our on-line 'Medical Genetics Lab' is inspired on constructivist learning environments, where students engage with a variety of cognitive tools that simulate a laboratory environment to obtain specific learning goals. The course contains original simulations of electrophoresis and is designed to supplement standard 'wet' labs, but illustrates a wider range of samples and procedures than would be frequent in these, thus making choice possible. Course content and learning tools (some original to this course, some borrowed) are described. The course was assessed by a class of 25 3rd year Genetics undergraduates at Trinity College Dublin, and is available free at http://www.tcd.ie/Genetics/staff/Miguel_DeArce_GE3095/Index.html

Introduction

Undergraduate laboratory sessions are meant to impart two types of knowledge; 1) 'manual skill', for instance, how to set up an electrophoresis rig, and 2) 'analysis skill', i.e. how a given problem can be solved with a technique, and how the results should be interpreted and integrated in the context of the problem. If lab sessions are not to be seen merely as mechanical repetition ('type 1' knowledge) of a set of instructions, it is essential that they capture the original experience of 'discovery by experimentation' ('type 2' knowledge), and that they make possible the recreation of this experience at will under the constraints of the academic timetable and the pressures of large numbers. We considered that in the transfer from the professional practice to the scholastic environment, the 'type 2' knowledge gained from the laboratory would seem to suffer a process of degradation, and that we should attempt to recover for the scientist in training the ever-fresh educational value that the laboratory has for the professional. This surely must mean; variety of problems, scope for judicious choice, immediacy of results, and guidance with their interpretation and professional context, i.e., an inter-disciplinary approach. Constructivist learning environments (Jonassen 2001, Jonassen and Carr, 2000), with their underlying philosophy of 'teaching by doing' have the potential to re-establish the educational balance in this case. This presentation describes an attempt to enhance (or in some situations, replace or create anew) a set of standard laboratory sessions on Medical Genetics with the assistance of on-line teaching (DeArce et al, 2002)

Course Contents and Assessment

Medical Genetics laboratory courses for undergraduates aim to illustrate human DNA variation associated with pathology. The strength of this association can vary, from simple genetic linkage, to a disease-causing mutation. Judging the DNA variation by size alone, this can be large enough to be visible under the microscope (as studied in cytogenetics), or small enough to involve just one base change, in which case it can be visualised using electrophoresis, including sequencing. It is peculiar to medical genetics to study how diseases segregate in families, i.e., the analysis of pedigrees. The possible effect of a mutation on the structure and/or function of the protein it encodes should be undertaken next, followed by an understanding of the role of the gene product in the pathways where it may be involved. This brief outline determined the contents of our course, divided into four chapters; 1) ***Cytogenetics***, to deal with chromosome abnormalities, 2) ***Pedigree analysis*** to extract information from family trees where a disease is segregating, 3) ***DNA sequence analysis***, including several forms of ***electrophoresis*** used to reveal sequence mutations, and 4) ***Protein sequence analysis*** to reveal the possible structural or functional effects of mutations. Table 1 enumerates contents in more detail.

Chapter	Cognitive Tools	Related cases	Learning goals
Cytogenetics	Photoeditor Colour picker Pathology databases Patient group websites.	20 photographs of banded metaphases from normal, cancer, constitutive and prenatal disease.	Karyotyping, (standard + varieties of FISH and multicolour karyotypes), chromosomal disease.
Pedigrees	Bayesian calculator in a Java applet.	>25 pedigrees illustrating patterns of inheritance, from recent literature.	Linkage, risk calculations, genetic counselling, modes of inheritance.
DNA lab	Original code (in php) simulating five types of electrophoresis, including Southern blots and DNA sequencing. Restriction enzyme analysis...	8 families where cystic fibrosis is segregating (12 mutations), plus 4 families with fragile X syndrome.	DNA segregation, mutation types,(including dynamic), compound heterozygotes, denaturing gels and other ways of mutation detection, PCR.
Protein lab	3D viewer.	External databases, including sequence and structural data, metabolic pathways, mutation ...	Structure-function relationships, primary, secondary, tertiary structure...

Table 1.- Learning elements in 'Medical Genetics Web Lab'. All non-original software or data are freeware, in the public domain, or are used with the explicit permission of the author.

The course was presented in Trinity term 2002 to a class of 25 3^{d} year Genetics undergraduates at Trinity College Dublin, on five one-weekly sessions at the public computer rooms, lasting 3 hrs each. Student assessment was through a written report submitted as an illustrated WORD document. The students' assessment of the course was obtained through an anonymous questionnaire after the last session, and is summarised in Table 2 below. We are encouraged by the positive opinions expressed by the students.

Item	Response (15/25 respondents)
Time required	10 – 20 hrs after class (for the four exercises selected, one per chapter, i.e. 2.5 - 4 hr/exercise, which is more than the time required for 'wet' lab sessions.)
Did you read the contents?	Yes (all respondents). Some said that reading was essential as text contained clear indications about the nature of the problem or tool.
Contents quality	Very good (4) but hard to read (2). Good, interesting (9)
Guidance quality	Very clear (7), sufficient (5). Some times confusing (3).
Opinion on this on-line course	Useful (6), gives better scope than lectures (2), interesting and novel (1), very informative (1), worked well (1), prefer lectures (1), was really impressed with this tool (1).

Table 2.- Summary of students responses to course assessment questionnaire.

Abstract: Adobe's Portable Document Format (PDF) is a versatile communication tool whose potential has not yet been fully realized in higher educational applications. PDF can play an important role in the way we go about conducting research and disseminating information. This poster presentation will outline the rewards of utilizing PDF as a multidimensional information tool in a research, distance learning and classroom setting. Various underused functions of PDF will be illustrated within an academic context.

Introduction

Exchanging research papers and ideas prior to the emergence of the Internet was often an arduous and slow process. It normally required a physical interaction that necessitates the emancipation of time and space logistics for both parties. Electronic mail and the WWW have alleviated this strain considerably, but not without shortcomings. System, platform, software and font dependence often results in a *lossy* exchange of data transmission and design as well as limiting the media used. Adobe's PDF has addressed these deficiencies by providing a way of packaging material developed in several applications into one standard format, readable by software that is free and easily available. The result is a *lossless* document with postscript printing precision, stable design integrity, and the ability to incorporate interaction and rich media. Higher education has been slow to embrace this versatile tool, partly due to tradition, culture and misinformation.

Presentation

The format of theses and dissertations has remained unchanged for over 100 years. The constraints of this format do not allow for the inclusion of rich media such as video animation. It also does not accommodate the ease and flexibility of non-linear narrative and referencing as seen with hypertext media?

The true potential of the PDF's capabilities may soon come to fruition at The Ohio State University, as well as other peer universities around the world. OSU is now moving towards exclusive electronic submission of dissertations and theses. The immediate benefit of using PDF is the advantage of being able to directly store and retrieve an electronic document with a fairly small file size. This format allows students to include hyperlinks and bookmarks within their document, thus making it easier to scan, reference, and navigate. PDF also gives students the option to incorporate dynamic elements such as audio, video and simulations, not attainable with traditional static forms of delivery.

Whether in a classroom or distance learning setting, PDF can enhance the teacher-student relationship. PDF may be used as a screen-based presentation medium as well as a printed document, offering students a very flexible option when delivering or documenting their research. An instructor who utilizes PDF in their regular classroom correspondence will be able to efficiently archive the student's thesis iterations and respond with direct feedback, with the ease of placing a "sticky-note." With feedback being a pivotal part of effective college teaching, PDF allows for effective distance learning interaction for all creative disciplines that have been hindered from previous methods of communication. For example, visual communication students can design using their own tools, submit their work electronically without alterations in the exchange, and quickly receive pinpointed feedback

Conclusions

It would benefit higher education to incorporate PDF as a communication standard for academics and research. Graduate degree candidates would be provided a richer arsenal for theses and dissertation completion, teachers and students can be empowered in the classroom, and distance learning for creative arenas can be realized or enhanced.

It is the intent of this poster to present the features and benefits of utilizing PDF as a multidimensional information tool. A variety of applied examples within an academic context will be outlined including dissemination methods and techniques, asynchronous teacher-student interaction, distance learning, integration of rich media, document archiving, and version tracking.

Abstract:In this new age of technology we face nowadays demands new experiences concerning education. Traditionally the word education means being connected to a educational institution. In this brief paper we summarize the initiative that our group undertook three years ago trying to build a different educational structure devoted to widespread technological knowledge based upon volunteer work. In this paper we present an introductory background , describes the methodology used on the project concerning the educational and technological aspects and present results obtained from the project

Introduction

---

[1] Bolsista do CNPq - Brasil

[2] Bolsista do CNPq - Brasil

In this brief paper we describe a small initiative that our group undertook three years ago in setting up a *structure that could keep up with this new reality of generate work force that matches the needs of government, private companies and others organizations.* We mixed aspects of educational theory like cooperative learning and informal learning connected with Internet technologies like email and discussion groups basically. The focus was basically oriented to advanced technologies like Object-Oriented Modeling, Java programming and Database modeling. We think that just introducing computer technology at school without rearranging the social aspects could be a misleading track. Informal education is a wonderful way to experiment with Internet technology. The group is composed essentially of volunteer professionals from the academic and industrial world that work everyday with these advanced technologies and are willing to contribute at the societal level.

Methodology

Every sunday we meet having classes from 9 AM to 15 PM. Nowadays we focus on the following courses: Java programming, Object-Oriented Modeling, Database Modeling and XML. The public is formed basically from the community, not being necessarily connected with a educational institution.This promotes a high motivational atmosphere. In general it is a very informal way of working and learning, and most of the classes uses cooperative work as their main educational tenet. This mixture have worked very well, because there is no stress concerning tests, and the students get much more involved in the process, as they see that can apply the knowledge in their professional lives. Nowadays we are using Internet tools like email and discussion groups, which facilitates the virtual communication during the week.

An extra activity in the form of a one day workshop is organized every three to four months. These events are partially sponsored by companies and local universities and its main guideline is connect the students with really important professionals in the field of information systems. They also foster the creation of a knowledge community. The last event was related to linux [One Day Linux].

Conclusions

Several results arosen from this experiment. The instructors have the opportunity of teach developing their own methodology and get much more confident on their work. At the moment the group concentrates on the modeling of a few tools like a portal and a learning management system. Our last internal statistics registered around 120 people working together in our community, and more than a hundred that had participated in some sense of the training.

Java-based Tele-collaborative Environment

Abdulmotaleb El Saddik
School of Information Technology and Engineering (*SITE*)

elsaddik@site.uottawa.ca

This work presents a software framework designed to provide transparent synchronous collaboration environment. The objective of this work is to develop a generic framework that can be easily integrated into other similar systems. The system supports not only Java applications and applets, but also Java Media Framework player allowing sharing multimedia applications in a transparent way. At the meantime, we developed client synchronization for the system in order to minimize the network transmission latency and let all the clients see the same view of the shared application at the same time. In our design, we add a session recorder to the system. The collaboration server is responsible for recording events while clients send events to others through it.

The approach behinds our concept, underlies the following requirements:

- No restrictions in the source code are required to share an applet. Both AWT and Swing-based applets should be supported. A solution restricted to only one kind of components is not acceptable.
- Applications using the standard Java-Core API should be supported.
- No new API should be developed.
- As less as possible of the network's bandwidth should be consumed.

The practicality of our architecture is proven by an implementation. We have developed a collaboration system, called JASMINE (Java Application Sharing in Multiuser INteractive Environments), which facilitates the creation of multimedia collaboration sessions and enables users to share Java applets and applications, which are either pre-loaded or brought into the session "live". The system also provides basic utilities for session moderation and floor control. Our approach applies to both applets and applications and hence these terms are sometimes used interchangeably in this document.

Figure 2 illustrates a sample screenshot of a typical JASMINE session. It shows the client's Collaboration Manager and some shared applets and applications running in the session.

As can be seen from figure 1, JASMINE consists of many utilities that enable multimedia viewing and sharing. The following section briefly describes these utilities.

Joint exploring of Java applets and/or applications

Users can use any applet on the web in a collaborative way. All they need is to specify the URL of the applet in an appropriate URL field or get it from a configuration file.

Joint Web browsing & Presentation

Using whatever java-based whiteboard, which can be used for shared color drawings, one has the ability to bring up presentations. Using Java-based browser, users at different locations can surf the web together. JASMINE is capable of bringing slides from the Web server and displaying them. These slides can be PowerPoint slides saved in HTML format, or simple sequences of images.

Pictures

JASMINE is capable of bringing up images in JPEG or GIF format from the Web server and displaying them inside the whiteboard. The users can then annotate on these images and start a discussion. The built-in locking mechanism of JASMINE is used to forbid modification of the same object at the same time by more than one user.

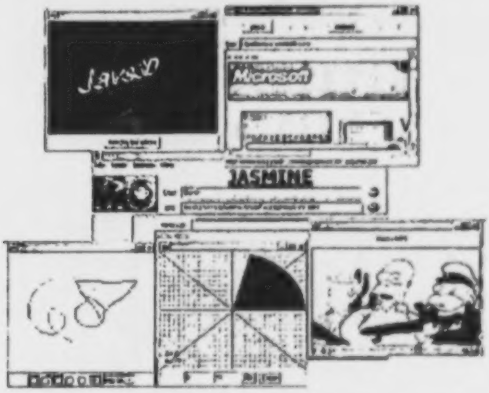

Fig. 2. A screenshot of a sample JASMINE session

Chat

JASMINE also facilitates user conversations by a having a shared chat space which can be used by participants to exchange textual massages. The chat space is useful in cases where audio access is not available.

Video

A very useful feature of JASMINE is its ability to play any JMF (Java Media Framework) supported video format. The video could be stored anywhere on the Web. When a user opens a video file and starts playing it, the video data is streamed down to all participants, decoded in real-time (processor permitting), and displayed on their JMF-based video player. Users can also play the video frame-by-frame.

Moderation

Managing a shared session is a very important ability, especially for telelearning. An instructor can use this ability to moderate a session, as in the real world moderation of a classroom or meeting.

History

The latecomer support lets latecomers get the current state of the shared application. However, sometimes latecomers may also be concerned about what events have happened before they join the session. Therefore, it is necessary to have a session recorder to record all the events happened since the beginning of the session and to replay these events on clients' demands. A session recorder is added to the JASMINE and as a result every client (not only latecomers) can replay all the events happened since the session began.

Accessibility Challenge to U.S. Government's Information Technology Initiatives

U. Yeliz Eseryel, School of Management, Syracuse University, United States uyeserye@syr.edu

Abstract: Section 508, an amendment to the Rehabilitation Act of 1973, establishes standards for electronic and information technology accessibility for Federal agencies. These standards provide criteria that spell out what makes products accessible to people with disabilities, including those with vision, hearing, and mobility impairments. To achieve such standards major changes in how we design must be instituted. However, Section 508 provides only general standards and the rest is open to interpretation. Moreover, due to the overabundance of technologies the task becomes too challenging. Besides, there is no one tool that can ensure total accessibility.

Introduction

Section 508 is an amendment to the Rehabilitation Act of 1973, published on March 31, 2000. It establishes standards for electronic and information technology accessibility for Federal agencies. These standards, cover various means of disseminating information, including computers, software, and electronic office equipment. They spell out the criteria to make these products accessible to people with disabilities, including those with vision, hearing, and mobility impairments.

The Section 508 of the Rehabilitation Act Amendments of 1998 requires the Architectural and Transportation Barriers Compliance Board (Access Board) to publish standards that set forth the definition as well as technical and functional performance criteria for electronic and information technology. The standards affect the Federal agencies' and the companies they work with; in development, procurement, maintenance and use of Information Technology.

Basically Section 508 requires all information that is available to individuals without disabilities to be available to the individuals with disabilities, too. To achieve such standards, major changes in how we design must be instituted. These standards provide criteria specific to various categories, including:
Software applications and operating systems
Web-based Intranet and Internet information and applications
Functional performance criteria
Information, documentation, and support.

Managerial Implications for Agencies

The enforcement of Section 508 began on June 21, 2001. Yet, many of the government organizations aren't still "508 compliant". Part of the reason is because the task is quite challenging. To make the matters worse, Section 508 determines only general guidelines, leaving the rest to interpretation. Government organizations are not only striving to serve the public in the best possible way, but also trying to foresee and avoid possible future lawsuits. Fortunately for the citizens and unfortunately for the organizations, accessibility is not a one-time effort. This means that not only do the organizations have to deal with the management of hundreds of Web pages and oversee contractors for usability and accessibility issues, but also, they have to do it on a regular basis.

The second reason why it is very challenging for organizations to be "508 compliant" is related to the abundance of technologies used by the users of Information Technology. For instance, the users use of different versions of browsers and software. Unfortunately, the tool organizations use to evaluate the accessibility of their web sites may enable one user to access the full content while disabling the total access of another user.

The IT companies did recognize the possible benefits that Rehabilitation Act in 1998. Companies are quickly founded to do Web accessibility consulting. Some built tools to validate accessibility and repair software. Some suggest that accessibility should be checked by human eye and some advocate the use of software instead. There are many tools, services and resources beginning from couple of hundred dollars to thousands of dollars. The choice of technology and tools become very important when the sheer number of web pages and software to be checked is considered.

Unfortunately, there is no one tool that ensures that one website or software is totally accessible. Human judgment is very important but depending solely on human judgment may be very inefficient. Furthermore, not every organization has the resources to hire a person or buy very expensive software and services.

The best solution for every government organization or government contractors is to first decide on the resources they have: Financial resources and time and expertise. After determining how much money can be tied every year for accessibility, agencies should decide whether they could allocate full time employees with sufficient expertise. Many government agencies also chose to form special departments or discussion groups focusing on Accessibility issues. The reactions to accessibility can go from using free accessibility tools to hiring consultants to creating an agencywide lab that will test different technologies. The basic lessons to keep in mind are:

- Accessibility isn't a one time effort,
- Accessibility requires planning, strict policies, guidelines and guidance
- No tool can solve the accessibility, human interaction and judgement should also be used.
- Even if consultants may be used, the ultimate responsibility lies with the agency.

Making the World a Softer Place: Healing Through Cyber-Stories

The development of the website, "Band-Aides and Blackboards" was informed by the needs of a diverse audience of children (both medically compromised and healthy), teachers, health professionals, and parents. Designed to house the stories of children with chronic illness and disability in order that healthy peers might better appreciate the nature of their lives, this Internet space is fundamentally a portal to their experiences, and to their prescriptions for making the world a softer place. It is the evocative, passionate, and often poignant words of children that hold the power to effect societal change.

The website offers children a forum to tell their stories—to share their words, and through them, their worlds.

In the Beginning

The website began with an invitation to children and their parents to participate as 'experts' of Band-Aides, with the hope that the children would submit stories for publication on the site. The data gathered in response to the invitation provided a peek into the nature of the their lives, and the themes drawn from that data reflected the complex reactions children have to disabling medical conditions.

Children with the physical stigmata of their medical conditions or treatments are very sensitive to the response of others to their "differences." Because electronic exchanges are blind to appearance, they provided a mechanism for these children to communicate freely without worrying how their appearance might filter an understanding of their words. Because the children did not need to "show their faces," the stories had the advantage of being true to their lived experiences. For example, one child responded to the questions posed without having previously received permission from his parents—permission required of children for inclusion on the site. When requested to ask his mother or father to take a look at the permission page and send consent, such permission was received with an addendum from his mother expressingamazement at the candor of his story. "Ever since Tyler lost his hair, he's been very private about his feelings. Yet he told you just how he felt." When barriers of time, space and visibility were removed, a cloak of anonymity was fashioned that providedhim a cover of safety from which he could freely tell his story.

While the advantages of electronic communication with children are clear, its limitations are important to address. For instance, there was no foolproof way of ensuring that the stories received were authored by the children. Or that the permissions given were composed by the parents. In addition, the written word is incapable of communicating the nuances of language that the nonverbal component of face-to-face interactions might have provided.

The Field of Dreams

Expectations of receiving many positive responses from children after invitations were posted were greeted with a resounding thump. Yet here, finally, was a forum for youngsters to voice their narratives. Like in the movie, the "Field of Dreams", this 'cyberspace' was built, yet the children did not come. Reflection on what seemed a dismal failure prompted a more aggressive publishing strategy. The site was submitted to all major search engines and announced on many disease-related sites. Large health care sites, several education and health care 'listservs', and over 100 elementary schools were contacted through e-mail. They were encouraged to review 'Band-Aides', and were informed of the resources that the site had to offer.

Informed Consent

The process of informed consent involved securing both parental permission and child assent. Because there are dangers associated with an Internet presence, a page was constructed that explained both the risks and benefits to parents (parent.html). Children requesting that their stories be told were assumed to be giving their assent to such participation on the website. Once both parental permission and child assent were assured, an electronic dialogue ensued, with focused questioning designed to flesh out the stories the youngsters submitted.

Initial Content Development

In an attempt to provide visitors with a sense of the experience of children with chronic illness at the onset of site development, data were collected from hospitalized youngsters about the experience of re-entering school after extended absence. Some of their comments were published on a page titled, "People Say and Do the Strangest Things" (teasing.hml), and others in a story fashioned around the data gathered about the first day of school for an eight-year-old recently diagnosed with diabetes, "Sally Goes to School" (sally.htm). These 'patients' were further offered the opportunity to serve as 'tour guides' on a series of pages designed to provide an introduction to the hospital. The hospital tour empowered them to communicate to their classmates their expertise about such clinical paraphernalia as pulse oximeters, oxygen masks, traction, and intravenous infusions (hospital.html).

In addition, some children shared 'tips' for health care providers, educators and parents when they did not have parental permission to submit narratives. These anonymous tips were crafted into separate pages. The cyberspace was growing, and the children were claiming it as their electronic home. The field of dreams was becoming a field of possibilities as they told their stories, shared their poetry, and revealed that the medical challenges they claimed did not define who they were as children.

The Growth of a Dream

Originally directed to an audience of elementary school children, their teachers, parents and health care providers, Band-Aides… received many stories and some powerful poetry from adolescents. This age diversity of childhood 'experts' suggested a need to divide the site into a section for 'kids' and another for 'teens' in order that the language used might be appropriately directed to each group. The teen introduction and invitation to participate were designed with that audience in mind. And the site grew.

Soon, requests to share stories were received from adults who grew up with chronic illnesses and disabilities. The stories communicated a wisdom borne of serious challenges and remarkable resilience. Because the counsel these adults brought to the site was of such great value, the site was further divided into a section for adults. They had 'been there, done that', and the suggestions they offered were applauded by youngsters growing up with illness. The adult pages soon expanded beyond individual narratives to include exemplars of parenting, tips from the children for parents, teachers, physicians and nurses, and additional Internet resources for that diverse audience.

Stories and Then Some

The narratives received were filled with passion, humor, frustration and loneliness. They revealed significant strength, and they communicated significant problems secondary to the social response of others to 'differentness'.

Too often, health professionals co-opt patient stories by translating them into the specialized jargon of disease talk; acronyms, laboratory values, algorithms of medication dosing. Even when diseases are effectively treated, patients may be left alone to struggle with the integration of the experience of illness into a coherent sense of self. The stories of the children argue against Because of the degree of stigma apparent in so many of the stories, pages were crafted around the nature of and response to teasing in an attempt to empower children with effective strategies for coping with it. One such page featured healthy youngsters advising children about how to deal with insensitive comments from their peers. These 'teasebusters' provided hints informed by both lived experiences and uncanny wisdom: "The thing is", one of them said, "everybody gets teased, so you just have to blow it off and don't let it bother you. Otherwise it'll get worse." (teasing2.html). Narrative discourse

As visitors to Band-Aides provided comments and suggestions, the site grew. Siblings wrote of their challenges growing up in the shadows of illness, (sibs.html); imagery was offered at the request of a mother whose son was dying of rhabdomyosarcoma, (yardin.html); lesson plans were constructed to offer teachers some guidance in curricular use of the site for elementary and middle school students, (sampler.html); poetry was written to translate medical jargon into language acceptable to children (e.g. leukemia.html), an orientation was constructed to the hospital for parents, (orient.html), and many interactive pages were offered to engage children as they visited the pages.

Many visitors to the site requested specific advice, much of it available on line, but seemingly hidden like needles in the haystack of the web. The most substantial page of Internet links was developed for teachers, so that they might better support students who come to school with significant medical problems. (http://www.faculty.fairfield.edu/fleitas/healthed.html)

Evaluation

Evaluation of the site involved requests for feedback of its structure and content from experts in web development and professionals in health care and education. As a result of structural feedback, navigation was improved, colors were used in a more complementary fashion, contact information was available on each page, forced music was eliminated and user-controlled audio files were employed, and alternative text was provided for all graphic images. As a result of content feedback, links were provided at the end of each narrative to allow readers easy access to disease specific information at credible health sites, terms were defined in developmentally appropriate language, and additional pages were developed to address needs defined by parents, teachers and health care providers.

Evaluation is ongoing, with letters from the following constituencies serving as a major vehicle for assessing the degree to which the audience-specific objectives have been met. A sampling of their letters follows:

- Healthy Children and Youth: The objective was to appreciate classmates growing up with medical-related differences. "I have wondered for a long time what kids feel like when they have serious medical problems. Your site helped me to understand. I also know now that if I ever meet someone who has an illness, it will be okay to ask them about it. It also makes me feel good to know that if I ever get very sick (which I hope I never do) I would have somewhere to go to for support outside of family and friends.
- Children and Youth with Medical Challenges: The objective was to become empowered as experts in this health education, and as a result, to experience less stigma in social situations. "I have become friends with people I never would have imagined, people from all over the country who are different in many ways--but similar in one. All in all, the site has helped me so much to know that there are other people who are out there with similar stories--other people out there to offer support to, and other people out there who understand what its like to be "the sick kid at school". I am a better person because of Band-Aides".
- Health Professionals and Educators: The objective was to appreciate the 'patient's voice' when studying disease entities. "I find that I am very apprehensive with the disabled students at my school. I like them, I talk to them, but somehow I am afraid of offending them in some major way. Unfortunately, I probably confuse them with my strangeness. I guess it's kind of guilt that I do not have to walk on crutches and wear braces, or depend on a wheelchair and deal with deformities. Or to adapt and deal with blindness and deafness in a visual and hearing discriminative world. I am floored! I am so happy to find your site. This is the kind of thing I have been looking for!"

The evaluation of the site continues, with plans to explore behavioral differences in children using the site in the curriculum with children not so exposed. Band-Aides and Blackboards is indeed a work in progress.

Interactive Simulation of Patients – An advanced tool for student activating learning in medicine

Uno G.H. Fors, Dept. LIME, Karolinska Institutet, Stockholm, Sweden, Uno.Fors@lime.ki.se
Rolf A. Bergin, Dept. LIME, Karolinska Institutet, Stockholm, Sweden, Rolf.Bergin@lime.ki.se

Abstract: During the years a large number of simulation systems have been developed for medical students. Many of these systems are designed for programmed instruction or other less student activating methods. However, we want to promote student activating learning methods allowing students to train clinical problem solving in a "natural" simulated environment. The ISP system is constructed in such a way that it might simulate virtually any part of the interaction between the patient and the users, including interactive video based dialogue using natural language, a full physical examination and laboratory tests. This system has been applied in courses at a number of Swedish Universities and also at Stanford School of Medicine.

Introduction

A large number of more or less interactive simulation systems have been developed during the years. Many of these systems are designed for programmed instruction or other user-controlling applications (Bitzer & Bourdreaux 1969, Bergin 1974). However, the pedagogical ambitions at the Karolinska Institutet have repeatedly and clearly been expressed as to promote the students abilities to solve problems, to promote the students beliefs in their abilities to solve problems and to present as clinical and integrated problems as possible. In the area of casesimulations, we have been developing student - activating learning systems since the 1970's (Bergin 1974). A new series of advanced simulation tools were developed at Karolinska Institutet in 1990:s, called Interactive Simulation of Patients, ISP. These systems are constructed in such a way that they might simulate virtually any part of the interaction between the simulated patient and the users, including an interactive video based dialogue using natural language, a full physical examination and thorough laboratory tests. This system has now been tested, used and refined in several iterations and applied in courses at a number of Swedish Universities and also at Stanford School of Medicine in the USA. This presentation will describe and demonstrate the ISP system and also present results from a number of student courses.

Methods

The construction of the ISP system is based on standard tools used to implement simulated patient cases. Every patient case is constructed based on a mix of real and fictive patient history questions, clinical photos of professional models acting as patients, X-ray images of real but anonymous patients and a number of other sources. No real patient images or videos are used. A team of teachers and clinicians are cooperating to construct a detailed manuscript for the illness history function, consisting of a number of hundred common questions and their corresponding answer. All cases are based on a "normal" case with normal lab tests and physical examination findings, allowing the developing team to only change the few specific data for all new cases. Further on, since all data, including the patient history video clips, answers, questions, laboratory data, X-ray images and physical exam results are stored in a central development database, it is rather simple to create new cases out of the extensive material available.

The ISP system has been applied in a number of different course settings in Sweden and in the USA. Most of these have been using different versions of the system (that is available in Swedish and English) and during different course settings for refinement, initial prototyping and also in routine courses. However recent course set-ups within the Wallenberg Global Learning Network have studied educational implications for both learners and teachers, using the latest ISP version. More specific, the ISP system was compared with traditional paper based cases to study the possibility to present good educational cases to the students and assessed regarding student-activation and clinical problem solving. The paper based cases and the ISP cases were developed using the same scripts and were of similar level of difficulty.

Results

The ISP system, which is designed to be used in student groups, contains these main features:
- A natural language, free text driven, patient history function with responses by digital video

- A detailed physical examination including inspection, auscultation, palpation, reflexes and more
- A complete set of laboratory tests, including more than a thousand lab tests, X-ray images etc.
- A user adjustable log function that tracks all interactions and an individual user notebook
- An interactive diagnosis proposal function, promoting reflective thinking and reasoning
- A detailed feedback function with comments on the interview, ordered procedures and resources used
- An information central with literature references, chat site and an integrated Medline search engine.

All functions are freely chosen by the user and are available at any time and in any order.

The user enters the interview question in free text using the keyboard. The system is using a large set of videos, which corresponds to nearly a thousand different question possibilities. Using combination of clips and a "semi-intelligent" data base function, the simulated patient can "react" on repeated questions and other unwanted questions by either show frustration, by becoming angry and even leave the physicians office. The simulated patient can also to some degree "spontaneously" interact with the user, especially if the user does not ask any questions for a long time. The inexperienced user can also use a built in help function to select predefined questions from a list.

The physical examination is steered by the user selecting what type of examination wanted (inspection, palpation, auscultation, temperature, pulse/blood pressure or neurology) and which body part to apply the exam on. Laboratory tests are ordered from a lab menu covering more than a thousand different tests (Chemical, Pharmacological, X-ray and other imaging labs, Microbiology, Immunology, Endoscopy etc).

Diagnose proposals are given using free text. If within acceptable limits, a short description of the case is given, including background and differentials. If an incorrect proposal is given, a short feedback on that particular diagnosis is given, followed by a possibility to continue with the case. The user is also asked to motivate the diagnosis. The user can at any time call for feedback. However, to avoid revealing the actual case's correct diagnose before the user has entered a proposal, feedback is limited before diagnosis. Additional feedback is also given in respect to performed unnecessary or potentially harmful investigations and regarding the cost of lab tests. The case simulations available today are concentrated in five areas, representing central issues within the education and to areas where important discussions on differential diagnosis could be held. All together, more than 20 different cases are available today.

During the recent courses, 40 students participated in Uppsala, at KI and at Stanford. The evaluation revealed that the activity at all three sites were greater as compared with the paper cases. Students were more active and asked more relevant questions regarding the case in the ISP session than in the paper session. Teachers and students reported ISP cases as being much more real-life like and more stimulating to work with than the paper cases. Most students were very positive to the ISP based cases and most of them stated that they would like to have more cases like ISP in their future training.

Conclusions

Most case simulation systems available are restricted in freedom of use and seldom allow a totally free interaction, especially in the case of interactive illness history. They rarely provide the user with most physical examination procedures and laboratory tests available in a hospital of today, limiting the applicability in a real-life-like clinical student activating learning setting (Bergin & Fors, 1992, Fors & Bergin 1996). The ISP system has been developed with the focus on a more free and interactive system, allowing most procedures and interactions available in a real patient case to be performed by the user. During the years, the ISP system has been used in large number of courses at many different universities in Sweden and elsewhere with good results as measured by student and teacher opinions. In this study, it was indicated that ISP has a large potential as a student-activating learning tool. Since highly interactive systems like ISP seems to activate students more than traditional methods, we think that learning outcomes might be better in comparison with more simple systems. This is a field for further research, which we are focusing our ongoing work on today.

Abstract: Until recently, most electronic materials for learning languages were developed standalone. Therefore, auxiliary materials were either developed only to play a subordinate role and insufficient in terms of quality and quantity, or required to be linked to available huge dictionaries on the market. When language learners could not solve given questions, they referred to these auxiliary materials which were considered thus rather unimportant. However, the authors feel that electronic materials need to have better auxiliary functions which provide learners with the exact information they look for, especially because they are often used as self-study guides without instructor's help. From this standpoint, the authors picked up electronic vocabulary and grammar materials that were used in an actual classroom, developed supporting e-materials that could work closely with them, and then measured the effects on learning. Here, the authors report the positive results based on the questionnaires after the one-year tentative implementation.

Introduction

In the past, the authors developed a classroom-aid system called "EDLIN (Educational system Developed for Learning on Internet and intraNet)" (see NAKAYAMA 2000) whose purpose was classroom support in LAN environment. EDLIN supported language learning in a computer room where every student was assigned a PC and realized an e-classroom by managing everything in an electronic format from student attendance to traditional classroom items such as blackboards, notebooks, textbooks and small tests.

As a self-study-aid system, the authors also developed vocabulary and grammar materials (see YANAGIDA 1999) that were available on the WWW and a system that provided classroom contents. The databases for the vocabulary and grammar materials were electronic versions of what the students used in a real classroom. Since the vocabulary and grammar materials were freely accessible from any computer with an Internet connection, the learners could always look up grammar and its detailed explanations, meanings and conjugations of vocabularies, example sentences, related words and etc. Also, the content providing system sent out recorded classroom videos which were synchronized with blackboard views on the EDLIN system. It served as a review source for the students and always allowed them to go back to the old classroom contents.

Using the above two systems in their learning, the students started to demand a drill type of materials for their class preparation and review. In language learning, it is important to learn knowledge such as grammar, but it is also necessary to remember that knowledge by using it repeatedly. For that purpose, a drill type of exercises is inevitable. In this project, the authors developed a system for those exercises that could be tried on the Web and integrated it into the existing classroom/self-study-aid systems.

For WBT (Web Based Training), it is important to provide knowledge related to given questions. Because WBT is often used for self-study purpose, it is necessary for the learners to obtain knowledge that helps to solve difficult questions they encounter, in which no instructor can help them face to face.

Up to today, WBT materials for learning languages have been developed standalone. Although auxiliary materials such as dictionaries and grammar books are offered in electronic forms, they are used as "subordinate" materials to "main" WBT materials, thus leaving their quality and quantity insufficient. Some auxiliary materials are designed to refer to huge dictionaries available on the market. These materials are satisfactory in terms of volume, but inconvenient to use especially for beginners due to their unnecessary information.

The authors developed the drilling exercise system and integrated it with the electronic versions of the vocabulary and grammar books that were actually used in the classroom, hoping to provide the learners with more useful information at an appropriate level.

The exercise system the authors developed this time is characterized as follows:

1. Since the exercises and the review materials (the vocabulary and grammar materials) are closely connected, it is possible to lead the learners to deeper understanding and more efficient learning.
2. The review materials are appropriate for the learners in both quality and quantity because they are electronic versions of what they use in the classroom.
3. It is possible to advise the individual students on their weaknesses if necessary, by saving their learning histories for every exercise and analyzing them. This function results in more effective learning.
4. By using multimedia such as animated/static images and voices, it is possible to provide the students with new learning methods that are different from traditional monotonous methods.
5. The teachers can offer self-made exercises on the exercise system by using the exercise editing system.

Abstracts of the exercise system

The exercise system offers four kinds of exercises.

1. Sentence composition exercises by rearranging word order
2. Vocabulary exercises
3. Exercises of four multiple choices
4. Listening exercises

The system also provides viewing learning history function for students and Management system for teachers.

Evaluation

The authors tentatively introduced the above mentioned exercise system in a German class that took place in a computer lab at Waseda University and assessed the effects by taking questionnaires. In this class, every student was assigned a PC.

As for the evaluation method, the authors first asked the students to use the exercise system and then collected their feedback by using a questionnaire page on the WWW. The number of valid responses was 85.

In Table 1, the authors show the five graded results in the five items: effectiveness for learning, operation, layouts, processing speed and sufficiency of the offered functions.

As shown in the table, every item was basically marked with four, indicating relatively high evaluation.

	1	2	3	4	5	average
effectiveness	0	6	10	46	20	3.98
operation	1	4	14	42	21	3.95
layouts	1	3	13	52	13	3.89
speed	4	4	17	42	16	3.75
sufficiency	2	2	16	46	16	3.88

Table1: Evaluation results for the exercise system

Back Ground

The e-learning is education used Video-Conference or WBT as a tool. WBT occupies the important position also in e-learning.

It is because it is the method for which WBT does not depend on the learning time or the learning place.

The importance becomes still higher by development of Personal Digital Assistant which has function the video recording and playing.

Most of WBT have adopted the system of the traditional CAI. The courseware which works on PC only moved to up to Web.

The so-called system of "Drill type CAI" is realized by WBT as it is. That is, WBT consists of questions which measure the explanatory note of the study item, and the learner's degree of comprehension.

This is the same structure as traditional CAI. Such structure cannot respond to an individual learner's understanding situation or point in question.

It can be said that this structure of the educational effect to the all learners is not large.

This research solves such a question, obtains the educational effect of WBT, and realizes "Intelligent CAI" corresponding to a learner's individual situation by WBT.

Outline

In order to perform this Intelligent CAI, in WBT, the correlation of an explanatory note and the question is set up beforehand. In process in which the learner advances study, after reading an explanatory note, it answers to the given question.

This method is performed per unit. And a computer evaluates the reply.

The process so far is the same as that of former type CAI.

In this WBT, it is dependent on evaluation of the reply result, and how to advance the following four study ways are set up.

1. When the learner understands very well, the learning system guides the learner to the following chapter.
2. When the learner understands in general, the learning system gives the learner some questions.
3. When the learner does not understand well, the learning system puts up the explanatory note again and gives the question for measuring degree of comprehension to the learner.
4. When the learner hardly understands, the learning system guides the learner to the chapter which can acquire fundamental knowledge.

By including these study ways in WBT, it enables the learner to receive automatically offer of the question according to individual degree of comprehension.

When it is considered that these four study methods are a student's understanding situations, it is expressed as S_1 to S_4.

The explanatory note of each study chapter is expressed as $C_1, C_2, \cdots, C_n$. The link place of the learning system to the understanding situation in each study chapter is expressed as $L(C_1, S_1) \cdots L(C_n, S_n)$

Table 1: The table of the link place corresponding to the chapter and the understanding situation

	S_1	S_2	S_3	S_4
C_1	$L(C_1,S_1)$	$L(C_1,S_2)$	$L(C_1,S_3)$	$L(C_1,S_4)$
C_2	$L(C_2,S_1)$	$L(C_2,S_2)$	$L(C_2,S_3)$	$L(C_2,S_4)$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
C_n	$L(C_n,S_1)$	$L(C_n,S_2)$	$L(C_n,S_3)$	$L(C_n,S_4)$

The link place corresponding to the learner's understanding situation in each chapter is determined by the logic based on a teacher's education strategy. We tried to make this logic program using the theory of Petrinet. Petrinet is because it is considered the optimal theory for corresponding to an uncertain situation like the learner's understanding situation.

Conclusion

Although we are developing this learning system now, to the learner's understanding situation and the ambiguous portion in instruction, we think that it cannot necessarily respond the optimal. Then, we are under the plan to add the fuzzy theory to this system as next stage of this research.

E-Learning Challenges: Digital Literacy and Creativity

Author: Marilene Garcia
Affiliation: Inter-Activa Educational Projects and Universidade de Belo Horizonte–Minas Gerais - Brazil
Email adress: marilenegarc@uol.com.br

Abstract
This paper is about the new expectations about E-learning in focus of developmdent of digital literacy with support of creativity.
For Glister (1997) digital literacy means "Proficiency in utilizing and manipulating information in online format and to process information from a variety of sources and formats so that one can create one's own knowledge path". In agreement with Glister, my thesis ist that E-Learning is per si a opened opportunity for development of many kinds of digital literacy and can be possible with emergent creativity. Dimensions of digital literacy include something more then instructional design for the content, more then pedagogical activities for students, or more then pedagogical goals for teachers. So the creativity must mean the way to get more then the tecnology can do for E-Learning.

Digital Literacy for E-Learning:

- New proposals for learning and teaching
- New ways of interating with others
- Emergent communities for educational proposals
- New attitudes and paths for educational interation and communication
- New social practices in educational communities

Creativity for Eletronic Education

Creativity is a complex process of generating ideas and it has to emphasize on eletronic education:
- Making a opportunity for innovation
- Making meaningfull new connections with usual things
- Making unusual alternatives, that your students are not expecting
- Mixing creative minds/ideas with technological support

Tools for E-Learning

The available and usual tools that teachers can use to make new connections and unusual things:
- www – Electronic educational enviromments
- Computer mediated communication: E-Mail, Chats, Newsgroup, etc
- Audio conferencing
- Document conference
- Desktop Video Conferencing
- Discussion List
- Interactive Multimedia
- Authoring systems
- Simulations systems
- Databases
- Course Editor Software
- Wordprocessing
- Metatools

Combination: Digital Literacy and Creativity for E-Learning

E-lerning has three principal components:
People – Teachers and students in collaboration context for learning
Educational Process – Pedagogical enviroment: resources, communication, content, goals and activities
Technologial Support – support for people and educational process
People + Educational Process + Technologial Support must be organized in a creative way to take meaningful action and to give good results.
People (in this case teachers) are not able yet to face the technological resources for E-Learning to make new decisions and to development innovative sinns.
Creative and multi-skilled persons are able to operate E-Learning products and tools, not only as users and but also as creator. There are meta tools (creation of other tools) available for this goal. Indeed they must deal with creative literacy skills.
Modes of communication (speech, writing, image, etc) have specific levels of representation in on-line educational enviroment and so People need specific knowledge and skills to deal with them. They envolve abilites and social practices related to the particular educational contexts and goals.

How People can Reach Creative and Multi-skilled Literacy for E-Learning Practices?

First level:Operate level – skills required to utilize electronic devices: softwares, several digital formats and hipermedia resources (Languages, tables, maps, diagrams, hipermedia navegation, etc), so people can be sure, to be able to do, to produce, to go further.
Second level: Communication/information/interactive level – skills required to participate of interacting in different types of commnunities, to change and produce information. The infomation can be dealed in multimodal forms: visual, writting and speech (visual, verbal, probelm oriented, communicative purposes).
Third level: Creative level – skills required to became a collaborator and a co-investigator in combining the other levels descripted above, to make creative choices and new decisions with focus on development of strategies for learning.

- Use the relevant discourse community
- Have a clearly defined learning purpose: Deciding where to go and where to begin
- Try to know better the audience
- Make good use of chosen resources and medium
- Find right people to change
- Dealing with time
- Choice and evaluating sources
- Dealing with metadata
- Dealing with multmodality
- Publish in hipermedia
- Searching for new tendences

Final considerations

Digital literacy and creativity can work together for E-Learning, when the educational proposal is looking for new answers with new resources for old teaching problems. The challenge ist to become a experts in innovation and to deal with common thing with a not common way, to start and to maintain a opportunity to go further on.

Interaction and EAD

The interaction matter is an essential point to be considered for the production of the software aiming the effectiveness in making decisions on line. It is therefore implicit a determinant behavioral character to spread information in case of interaction.

The interaction fundaments used in this study are the latest trends discussing the efficaciousness of education by means of new technology (PETTERS, 2001), pertaining to presence, half-present or at distance.

> *"It is good to vary, specially to frustrate the curiosity of the envious; hence they shall see the uniformity of our actions they shall take advantage of the foreseeing (...). It is easier to kill a bird that flies in a straight line rather than the one that does not (...).*
> *A real player shall never play the card that is expected by his opponent even less the desired one". (Gracian in Fayard; preface)*

The inference of the author (Gracian) makes us think about the importance of the development of new perceptions in relation to the other, expressing a different expectative, a change of what one has already lived. It is a phenomena of the necessity of change, of the unthought-of, the unpredictable leading to the construction of a new "Man". A MAN turned to the multiplicity perception, a being to be socially built for the acceptance of the differences. A Man that now inhabits a virtual environment and therefore needs more than ever an efficacious strategy of communication to survive.

We are facing a paradox, everything that was done strategically until today aimed the dominance. On the other hand, in the Western world nowadays, before this global virtual world, the way of thinking must be transformed to generate efficacy in the face of new problems. The reality of our times, more interconnected than ever in all different areas such as communication, information or simply forking off borders, does not allow segmentations .The problems are no longer individual problems, but collective; it is required co-operative solutions of systemic and complex nature because at the same time it depends on a part and on the whole.

Nowadays, the ideas of EAD, involving specially the virtual environment, are surrounded by paradigms that come from conceptions of present teaching and also from concepts of distant teaching that gives, in fact, a sense of distance but not disconnection.

The analysis of the environment, considering its conceptions of EAD (even turning the decision maker in specificity), make us believe in the idea of an EAD turned into what (PETTERS, 2001) calls "third generation" and because it is an ambivalent didactic (in the sense of overcoming the first two generations of EAD) has transformed its traditional conceptions of learning and teaching. This is because it offers orientation to the student (or user) that studies alone or with the help of didactic software, interactivity (as another means of making the construction of the knowledge more effective) and also making the database available in the search of information.

EAD Generations: The 1st generation is strongly based in the traditional paradigm of teaching and learning where learning happens by means of reading printed paper, guided studies and autonomous scientific work among others. The 2nd generation is based in the possibilities of teleconference. The 3rd generation of EAD, proposes an idea of interaction among the subjects; and among them the technology and knowledge, under the view of space and time, give the possibility of co-operation.

Interaction, while means for a better distant learning, shall be seen by the mentors of the virtual environment(aiming the education or not) as a cognitive strategy to promote autonomy, the exchange, the resolution of problems and decision making to propose the growth of the person towards a more dynamic view directed to a multiple and multicultural reality.

Vygotsky emphasizes the social interaction as a means of a better construction of meanings while for other authors, such as *Ausubel and Piaget, it is* emphasized the individual. As for *Vygotsky*, it is neither the individual nor the context that really matters but their interaction.

According to Garton *in* (MOREIRA, 1996)

> *"A definition of the social interaction means that there are at least two people exchanging information. (The pair is the smallest microcosm of the social interaction. It also implies in a certain degree of reciprocity and bi-directionality among the participants, meaning that the social interaction assumes active involvement (although not necessarily in the same level) of both participants from this exchange, bringing to them different experiences and knowledge in a quantitative and qualitative way."*

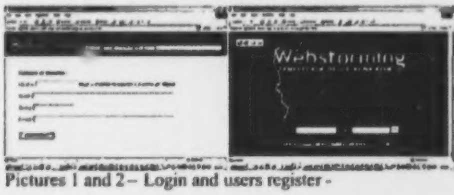
Web storming: Brainstorming in the web

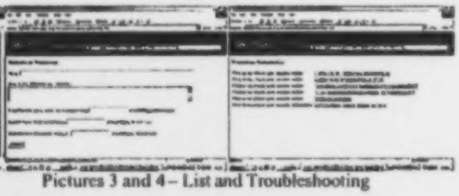
The tool proposed may be used in many situations, such as group dynamics, in which people with equal opportunities in an organized way, can give opinions about a certain problem, finding causes and suggesting solutions. Initially, the barriers found for development were the language choice and learning. The environment was developed with PHP and HTML languages and the software Dreamweaver and Fireworks.

The system is found at URL http://www.pgie.ufrgs.br/webstorming in continuous development and validation .

The user is able to register and log in to access the web (pictures 1 and 2), being able to use the troubleshooting or helping in solving some problems(pictures 3 and 4). When using the troubleshooting, the user defines three dates: the first to start the webstorming session, the second to indicate the deadline to register the ideas and the third to indicate the end of the voting session, to define the chosen ideas



Pictures 1 and 2 – Login and users register -



Pictures 3 and 4 – List and Troubleshooting

The user shall participate in the troubleshooting, registering ideas (picture 5) and at the same time verifying the ideas posted by other participants of the discussion. In picture 6 we are able to see the screen with ideas for the voting. When the deadline is reached for voting and registering, the environment shows the elected ideas with the respective number of votes.

In the environment developed, the main aspects of a conventional brainstorming session were maintained to guarantee the essence of the method. We shall observe that all participants are free to express their ideas, creating a nice environment to exchange different points of view, of the different persons, about different subjects searching for a consensual solution.

To the webstorming, the original idea of Osborn is attached, where mechanisms shall permit a decision making via web, adapting the known technique to a new reality of the virtual environment.

Conclusion and Future Works

The system is in the process of validation and some are being implemented in search for improvement. Below some future Works:

Limit one vote per participant in each session of the webstorming;

I) Allows the alteration or exclusion of users, problems and ideas;
II) *The deadline for the voting shall be sent via email, so that none forgets voting within the due date.*
III) After the voting ends, the environment shows the proposals that were most voted and shall make available a space for comments about the winner.
IV) The proposition chosen could be sent via email for all participants of the discussion that will know the results.

The webstorming is being tested by groups of some institutions, in search of data for analysis and improvement of the environment. It has proved to be, in tests done previously, a tool that can really help in the EAD environment, acting as a mechanism to help in the decision maker of the web. From simple actions such as the definition of date and place to meetings where people see each other, up to more important decisions, for example the choice of the subject in a colloquium. The webstorming was used then, as a means of making the ends meet.

In situations where there are no specific aims to obtain a final decision, the webstorming can also be used to help in the pedagogical characterization of team profile or even of participants. They can check the most discussed subjects in a chat, for example.

As new tests are being done, greater practical applications will be found for our software. In all of them, however the Idea of helping the users to make the ends meet in matters worked in virtual environment such as the EAD.

From Turnstiles to Cyberspace:
Perceptions of Librarians in an Era of Transformation

Change is prevalent in most academic libraries at present. Faced with the ubiquitous innovations of the information age, the librarians' traditional role can no longer hold sway. While colleges and universities attempt to compete with technologies that cut into the bottom line of libraries, little (if any) attention has been given to the perceptions of librarians and how they are reacting to change both emotionally and behaviorally. Emphasizing the captivating quality of naturalistic inquiries, the proposed study intends to contrast the differing perceptions of main librarians and special librarians.

The initial aim of this inquiry was to find an answer as to why there was more student circulation at special libraries than at main libraries. At the surface level, it was obvious that users visit special libraries more regularly because large tomes, such as legal texts predating the advent of the Internet, could best be accessible in the stacks. In the search for understanding, various sources were reviewed to learn whether this trend was exclusively endemic to the setting under investigation.

After reviewing extant literature, however, the object of the inquiry shifted slightly. For the most part, the reviewed literature hardly revealed how librarians perceive new technologies as one of the most serious factors influencing the elimination of numerous jobs forcing them, in some cases, to return to school in order to upgrade their academic skills. The aim of this scholarly manuscript is twofold: to analyze the intellectual, social, and economic stressors shaping the emergent role of librarians; and to conduct an inductive, comparative analysis in selected sites by collecting information whose findings could possibly be transferable to similar academic library settings.

As a departing point, literature on the subject will be reviewed to determine whether the taken-for-granted role of librarians has changed as a result of new information technologies. Subsequently, the proposed case study will be framed within a fitting philosophical paradigm. Such correlation is crucial because it should guide the methodological direction the study may take. In fact, it is expected that the role of the investigator throughout the study will be that of a co-participant, and that the planned open-ended interviews will be interactive in nature. In this sense, the study may serve as a catalyst for possible institutional change. When appropriate, differences and similarities across the studied settings will be illustrated through recorded examples not only to show how the perceptions of librarians may be directly affected by those conditions, but also to substantiate how such perceptions and attitudes could either foster or deter the espousal of new research technologies within library settings by professors and students alike.

Consistent with the traditions of interpretative hermeneutics (Denzin & Lincoln, 1998; Erlandson et al., 1993) the contextual analysis resulting from this investigation (i.e., its ultimate discourse) will be open to review to promote meaningful change within the settings and possibly in similar institutions of higher education elsewhere. It stands to reason, then, that this philosophical correlate; namely interpretative hermeneutics, would appropriately correspond with the characteristics of the critical theory paradigm, for the overarching goal of the inquiry is to promote meaningful changes within the settings.

Creswell (1998) states that, "[v]ariants of critical theory abound in all of the social science disciplines, but central themes that a critical researcher might explore include the scientific study of social institutions and their transformations through interpreting the meaning of social life…" (p. 80). Within the critical theory perspective, the focal point of this instrumental case study will be the analysis of librarians' perceptions as these are influenced by information technologies.

Within the Symbolic Interactionism perspective, the findings may also provide some insights into the way librarians "act toward the physical objects and other beings in their environment on the basis of the meanings that these things have for them" (Denzin & Lincoln, 1998, p. 233). As expected, the findings should reveal how computers have redefined the role of librarians as well as influenced their perceptions. In addition, because there is an ostensible connection across philosophical stances whose goal is to promote [needed] social change, it is anticipated that the overall outcome of the inquiry will also show some characteristics of Action Research (Berg, 2001) given its projected methodological construct "where creating a positive social change is the predominant force driving the investigator and the research" (p. 179).

To the ordinary observer it may be obvious that more students visit special libraries more frequently than main libraries. However, treating such differences peripherally (i.e. via spreadsheets) would not necessarily explain why such disparate circulation patterns exist. To better understand the phenomenon at hand, the researcher is willing to dig deeper into the layers of these structures in order to study, document, and interpret elements that may account for such differences. Whereas a quantitative approach may fall short when analyzing this trend, the proposed research, framed within the qualitative tradition of inquiry, would be a more befitting investigative tool to use in this case.

As reviewed in extant literature, the pervading influence of the Internet has already redefined the role of librarians both nationally and internationally. Yet, when applied to specific microenvironments, this external influencing factor may not be the only culprit responsible for a decreased student circulation, especially at main libraries. Therefore, the emphasis of this inquiry is twofold: to explore how librarians perceive their emergent role in the midst of changes propelled by an era of digitization and to compare how such perceptions may vary according to social, economic, and intellectual differences across library settings.

The primary sources of data collection will include thorough transcribed interviews, running notes of site observations, and resulting memoranda. In addition, relevant data extrapolated from archived notes (mostly in the form of electronic messages) will be used to corroborate data collected from the previously cited sources and to assist the researcher in verifying such data by triangulating the findings (Creswell, 1998; Denzin & Lincoln, 1998; Milinki, 1999). It is anticipated that by employing the method of triangulation the confirmability, credibility, and ultimate transferability of this study will be enhanced. In addition, because the inquiry is not framed within a positivist framework, it is also predicted that its outcomes may not be necessarily generalizable to other settings, albeit possible structural similarities, because such findings may be exclusively descriptive of specific characteristics of the studied milieu.

Next Generation Courseware: Custom Learning Environments Integrating Research and Collaboration

CHEF Introduction

CHEF (for CompreHensive collaborativE Framework) is a framework designed to expand the paradigm and functionality of course management systems by taking the approach of working to support the activities of scholarly and learning communities over time, in addition to supporting the administrative efficiency we are mostly familiar with. The CHEF framework has been built using (as far as they have been known) and developing further the Open Knowledge Initiative's APIs. And CHEF is being developed as an open-source project, intended to be collaboratively developed, customized, and implemented at universities across the world.

The first CHEF implementation is a complete re-design of the University of Michigan's course management system and is called CourseTools.NG (for Next Generation). CourseTools.NG is currently supporting a second pilot semester of nearly a dozen courses with approximately 500 students.

CHEF Architecture in a Nutshell

CHEF is a Client/Server system. CHEF services run on one or more CHEF servers; clients use various means to communicate with the servers to access CHEF. CHEF is a multi-user system, and has features that surface the presence and activity of the current set of users to each other.

CHEF uses the practice of *separation of concerns* to introduce various metaphors used to organize the development and functionality of the system. These metaphors include *tools*, *services*, *interface technology*, and *portals*. CHEF also uses the *Model View Controller* practice, i.e., services handle all modeling while tools handle controller aspects and generate views which are rendered by a template interface technology.

CHEF Project Overview

The CompreHensive collaborativE Framework (CHEF) Project has as its goal the development of a flexible environment for supporting customized learning environments and collaborative work, and doing research on learning and collaborative work. This will involve the identification, design and development of a framework that can effectively accommodate various tools that are used in supporting collaboration, research and learning, and tools necessary for the study of collaborative work and learning. The framework needs to provide organization for the disparate functionality used to support research, collaborative and learning activities and be able to combine locally developed, commercial off the shelf and free off the shelf components.

The initial communities of use that CHEF is targeting include those involved in the scholarly activities of teaching, learning and research at the University of Michigan, and their students and colleagues involved in teaching, learning and research that are outside of the Michigan community.

CHEF is aimed at making available a set of functional elements that can be easily configured by users to accomplish a wide variety of activities. This framework will support existing and emerging capabilities, and will seek to make the integration of new functionality as easy as possible.

In our past and current work we have seen much commonality among the needs and tools used by people in research and teaching/learning communities, and we are seeing the emergence of frameworks for user configurable toolset delivery. CHEF will mobilize our experience, research and user feedback in the effort to develop a comprehensive framework to support these scholarly activities, and make this framework available for wide use through an open-source model.

Implementing CHEF: CourseTools.NG

CourseTools.NG is an enhanced version of the original UM.CourseTools, with improvements that will include greater customization options for users and better support for a variety of pedagogical approaches. Examples of these include individual personal portals (referred to as MyWorkspace) in addition to class portals, the possibility for authentic assessment and e-portfolios, and new capabilities like presence and configurable group collaboration space.

These changes are the result of feedback we have received from individual faculty members, students, focus groups, and surveys. The current pilot phase presents some of the basic CourseTools capabilities within a portal environment in order to gather usage experience which will further guide development efforts.

Proposal for

Supplemental instruction and assessment elearning of difficult OOP concepts

Kenton Graviss and Ghansham Manwani

Indiana University Southeast

New Albany, IN, USA

At Indiana University Southeast the computer science curriculum includes two beginning-level programming courses: C201, Visual Basic programming and C202, C++ programming. These are required for all CSCI majors and C201 is also taken by non-computer science majors from the Schools of Business and Natural Sciences. They are, however, very different in their approaches to programming. The first course (C201) teaches the imperative or sequential programming paradigm, while the 2nd course (C202) teaches object-oriented programming, OOP. There is a significant paradigm shift between these two approaches - one that student feedback has indicated is a difficult one for them to bridge. This is because of the significant differences in programming concepts and implementation details students need to master for writing the two different types of programs. Clearly, a need exists to supplement the normal instruction beginning computer science students receive to help bridge the gap in understanding between the two types of programming. This proposal describes an approach we think would be effective for providing the required supplemental instruction as our students transition from imperative (i.e., procedural) to object-oriented programming.

Specific objectives that will be accomplished.

To facilitate the problem-solving shift from one programming methodology and compiler to another, we propose developing and creating supplemental instruction using AVI / multimedia files accessible from a web page that would deliver the supplemental instruction from the Internet. Students will view graphically-detailed and presented supplemental instructions, including videos online to get additional coverage of the subject matter that is intended augment their understanding of the most traditionally difficult concepts for them to master. These concepts include,

- The Integrated Development Environment (IDE)
- C++ semantics and meaning (language development)
- Recursion
- Object-oriented design (classes, encapsulation)
- DMA (dynamic memory allocation)
- Function prototypes (modular design)
- Searches and Sorts
- Algorithm analysis

Specific instruction files, each requiring approximately ten to fifteen minutes to view by a student, will be produced using current PC-based and graphic and digital video processing methods and technology. The files will consist of both static and dynamic screen displays that will be sequenced together with appropriate voice-over and background audio relevant to the subject material. Each supplemental instruction file will be presented on a web page devoted to the C202 course sections in the Fall 2002. On the web page, after each file has been completed by the student, they will be given a short quiz to test their learning from the supplemental instructions. In addition, they will be able to "roll back" and review material in the files at their discretion to go over material and concepts requiring more time for them to assimilate.

Methodology employed to accomplish objectives

Multimedia files containing static and dynamic (i.e., video) display content that include voice-over instructions and explanations, graphics, and text that will be made available online immediately preceding or following coverage of the corresponding material in the C202 course. The screens and videos will be geared to going over and reinforcing object-oriented concepts in new ways and from new angles that will connect to students by virtue of the multi-sensual exposure and inculcation of the supplemental instruction presentations.

Evaluation process

Effectiveness of the supplemental online instructions will be measured in several ways. First, student learning will be measured in two of the Fall 2002 C202 classes online using a web-based quiz integrated into the web page and offered at the end of each of the online supplemental instructions. The third Fall 2002 C202 section will not have access to the online supplemental instructions, and will serve as the control group for this study. The intent here is to obtain early and ongoing measurements between two classes of the effectiveness of the online instructions in assisting student learning of the most difficult concepts of object-oriented programming. By comparing the quiz results for two classes we'll get an indication of the variation in effectiveness by class.

Second, pre-assessment / post-assessment tests will be given (without grading) to all C202 sections at the beginning and end of the semester to determine what they knew before and after taking the course. The test will contain multiple choice questions intended to determine what they know about C++ and object-oriented programming concepts, including the most difficult topics that the online supplemental instructions are designed to assist with. The test results will be compared to determine whether students receiving supplemental instruction score higher than those that didn't.

Third, a follow-up, qualitative learning survey will be conducted at the end of the semester in all C202 sections in which the students will be asked to quantitatively state (on a scale of 1 to 6) how much they think they know about the topics supplemented by the online instructions at the beginning and at the end of the classes. The results will be compared between those that received supplemental instruction and those that did not to get another measurement of the effectiveness of the supplemental instructions for student learning.

Required technology and media

PC-based audiovisual technology, and media to design and construct the multimedia files required for posting on the supplemental instruction web page. A Dell 4100 Dimension video-processing PC is the primary platform for this research. DV Storm© video processing system (hardware and software including Adobe Premiere 6.0) will be used for instruction file development. A digital video camcorder will be used to create the videos that will be an integral part of the online instructions. Students will also be able to access the files from the Internet at any convenient location and time.

Additional details

Screen graphics and videos will be prepared using scripts as guides to highlight and enliven the OOP material. The goal was to design the instruction files creatively so as to enhance student interest and retention of the subject material. Thus new and novel approaches to combining graphic design and video editing were used. Our intent is to examine the results of the measurements and determine the effectiveness of this approach for improving student learning. If proven effective, as we expect, this methodology could serve a similar function in other computer science courses and courses with detailed and difficult-to-grasp-at-first technical content, as in many natural science courses.

Developing Reusable Learning Design Resources

Barry Harper, Ron Oliver[*], John Hedberg, Sandra Wills, Jan Herrington[*], Garry Hoban, Lori Lockyer, Catherine McLoughlin[**] & Shirley Agostinho

University of Wollongong, Australia

[*]Edith Cowan University, Australia

[**] Australian Catholic University, Australia

Abstract

An Australian federally funded project, ***Information and Communications Technologies and their role in Flexible Learning***, aims to produce generic/reusable learning design resources to assist academics to create high quality, flexible learning experiences for students. This poster provides a summary of the project activities in order to achieve its purpose.

Project Aim and Deliverables

This project aims to produce generic/reusable learning design resources to assist academics to create high quality, flexible learning experiences for students. This is to be achieved by:

- Identifying high quality learning designs used in higher education;
- Selecting those that are suitable to be redeveloped in the form of reusable software, templates and/or generic guidelines; and
- Developing these reusable resources and making them accessible from a central web site (which will be hosted by DEST).

The term "learning design" refers to a variety of ways of designing student learning experiences, that is, the sequence of types of activities and interactions. The scope of a learning design may be at the level of a subject/unit or subject/unit components. This project is focusing on learning designs implemented with the use of ICT and how flexible learning opportunities for students can be afforded through the use of such technologies. The composition of a learning design, particularly when ICT mediated, has been informed by the work of Oliver (1999) and Oliver and Herrington (2001). Thus, for the scope of this project, a learning design, comprises three key elements: the content or *resources* learners interact with, the *tasks* or activities learners are required to perform, and the *support* mechanisms provided to assist learners to engage with the tasks and resources.

The project began in November 2000 and is structured against four milestones:

- *Milestone One (May 2001):* Development of the Evaluation and Redevelopment Framework
- *Milestone Two (November 2001):* Identification and documentation of learning designs that foster high quality learning experiences and that have the potential for redevelopment in a generic/reusable form.
- *Milestone Three (June 2002)*: Design of the final project web site and completion of development plans for the generic products to be produced.
- *Milestone Four (December 2002):* Completion of the development of generic/reusable learning designs in a more generic form and finalisation of the web site that will store these resouces.

Major Project Activities

Development of an Evaluation Instrument - Evaluation and Redevelopment Framework (ERF)

The purpose of the ERF is to identify ICT-based learning design exemplars that foster high quality learning experiences, and to determine whether these exemplars have potential to be redeveloped in a more generic/reusable form. (The instrumentation is available at www.learningdesigns.uow.edu.au.)

High quality student learning is purported by this project as having potential to be achieved by applying four key principles (Boud & Prosser, 2001) in a learning environment: *engaging* learners, acknowledging *context*, *challenging* learners, and providing opportunities for *practice*.

Applying the ERF to Learning Design Exemplars

The project has identified over 50 ICT -based learning design exemplars and 28 were selected for evaluation. An ERF evaluation iteam comprised international educational technology and/or pedagogy expertise. Two evaluators were allocated to conduct an evaluation for each learning design exemplar.

Developing reusable Learning Design resources

To ensure the learning design exemplars evaluated represent a range of learning designs, the project team has developed a Learning Design Categorisation Framework. A number of exemplars have been identified as suitable for redevelopment in a generic/reusable form. The project development process comprises activities such as designing and developing the web site and developing and evaluating the generic learning design resources.

Development of Chinese language multimedia teaching material with a partial perception system utilizing 3D virtual space

Hiroaki HASHIGUCHI, Shinich FUJITA, Da Yang, Ming Yin, Seinosuke NARITA
Waseda University
3-4-1, Okubo, Shinjuku-ku
Tokyo, Japan
hasiguti@narita.elec.waseda.ac.jp

Abstract: It is common for educational materials used in conventional language education to begin from such elementary structures as "Hello!", "This is a..." or "Is this a..?". However it has not been sufficiently explained, pedagogically, what we begin learning in such an order or at such a stage. On the other hand, it is important to consider how we acquired our mother tongue. If a foreign language learner can learn just as we acquired our mother tongue, it is possible for learners to study efficiently and memorize words or expressions. In this paper, I would like to explore the feasibility of connecting language education and spatial perception by using 3D virtual space.

Introduction

When looking from the perspective of language learning, the textbooks that we traditionally used to start studying a foreign language began from such greetings as "good morning" or "hello". And we move into what we call elementary grammatical studies such as, "This is a pen." or "Is this a pen?". In the particular case of Chinese, the first section of most textbooks begins with "hello" and "thank you". Then, in the following order, come "temporal expressions" to "place expressions", "aspect", "can do..." and "passive/causatives". However, with the advance of cognitive science and cognitive linguistics, it has become clear that many of the words generated in abundance in our linguistic lives have a very profound connection with our experience and recognition of space that surrounds us. For instance, in terms of visual function, we achieve recognition in order of "light", "color", "one dimension", "two dimensions" and "three dimension". By two to four year olds, it is generally said that such adjectives as "thick" or "thin", which describe an amount three dimensional space, are used less frequently than two-dimensional adjectives such as "long" or "short". In addition to this, it is also understood that we come to recognize the "fourth dimensions (time)" after we have recognized such things as space. This is because, such expressions related to space as "before" or "after" that involve such space as "day after tomorrow", "three days ago" or "four days after" are frequently converted in the concept of time. In other words, the expression of space becomes the core of various words. For these reasons, acquiring spatial expression, felt by mankind through the senses, is indispensable in learning languages. In this system, I have decided to justify this learning theory using courseware that utilizes 3D virtual space. Research and development of multimedia educational materials using computers have been carried out in various countries, and their functionality has been improving year by year. Most of them fully utilize such characteristics of the computer as image, voice and network. Above all, I will strive to create a more effective system in which one can acquire practical expressions through the senses, with the learner acquiring a foreign language successfully. I hope it will be of help to progress in and to change language education in the future.

In development

In terms of pedagogy, research focusing on using VRML has been carried out for educational materials that use 3D. However, the reality is that the movement of fine areas cannot be expressed sufficiently with

VRML. For instance, Wolfgang Broll and his associates have realized 3D space using VRML [1]. The picture in their system is easy to look at, on the whole, but animation in such fine, detailed parts as hand or leg movements is not sufficiently expressed. As this system is aiming for something where one can acquire words using the senses whilst experiencing realistic space, I have decided to use Director8.5 by Macromedia, where the realization of fine, detailed 3D space animation is needed [2].

The system

I will explore how much impact this system has by having learners who have never studied Chinese take all five lessons of this system, and then evaluating them. The learner is to experience 3D space as a newborn baby would, in line with the curriculum indicated in the following. In addition, by repeating the process of moving by him or her self or touching things, the student is to learn the language. Subjects for all five lessons will be prepared for the learners.

First lesson: New-born. One begins to recognize things that surround one.
As newborns, we gradually acquire words through use of the senses by understanding the situations and things that surround us. Based on this premise, the lesson will have the learners experience similar circumstances (Figure 1). For example, after birth, a baby first meets parents and siblings, and then performs such actions as drinking milk. If we do to so, we acquires appropriate words through the senses. This lesson will have the learner experience similar circumstances.

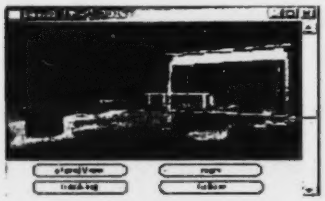

Figure 1 : Sample of this system

Expected result

There are two possible results anticipated here. First, learning time could be shortened. Secondly, it is conceivable, even with regard to such expressions as "temporal expression", and "localization of nouns", which were difficult to master in a traditional place of learning, that the learner will be able to form such expressions independently. This latter application, mentioned above, is something we see frequently in our daily lives. For instance, when we think of the expression, "up" or "down", if we have acquired the knowledge in 3D space through the senses that we climb a flight of stairs, when we encounter such a phrase as "pick up", we can imagine what it means immediately. In this way, expressions that have been acquired through the senses have a very wide range of application. Although "good morning" can only be used as a greeting, the expression "up" or "down" can be used in various phrases.

Building a Community of Learners and Encouraging Discussions in a Purely On-Line Course That is Quantitative in Nature

Jay S Holmen
Professor of Accounting & Finance
University of Wisconsin—Eau Claire
Eau Claire, WI, USA
Holmenjs@uwec.edu

Abstract: Teaching an on-line course can be challenging, especially one that is primarily quantitative in nature. How can we help the students to feel they are not alone, but rather are part of a community of learners? What do students discuss in a number-crunching course? Five elements were designed into the course to encourage student participation and a feeling of belonging. They are: 1) development of a personal homepage, 2) weekly discussion topics, 3) a course-long collaborative project, 4) a designated area to ask questions of the instructor, and 5) an area for the students to have open-ended, unstructured discussions.

Teaching an on-line course can be challenging, especially one that is primarily quantitative in nature. One challenge is the asynchronous nature of the course—the students are not communicating at the same time. How can we help the students to feel they are not alone, but rather are part of a community of learners? How can we prevent the course from feeling like 25 courses of 1 student each rather than 1 course of 25 students? A second challenge is in fostering discussion in a course that is primarily quantitative in nature. What do students discuss in a number-crunching course? This paper will discuss several approaches that have been taken in addressing these challenges as they relate to teaching an accounting course.

The Context

The course I teach is an accelerated, graduate only Principles of Accounting course offered to students seeking admission to an MBA program. Since the course is graduate level, all of the students are "adult learners." The students all have a common goal—admission to an MBA program. Since the course is a foundation course for further business study, the student population is more diverse than in similar undergraduate courses. The students all hold degrees in a non-business field.

The course is offered by a consortium of schools in the University of Wisconsin System. The pre-MBA foundation courses are all offered using on-line asynchronous delivery. Once admitted to an MBA program, most of the students will take a majority of their classes on a physical campus. The course delivery platform currently in use is BlackBoard 5.

Accounting is a subject that emphasizes quantitative skills. In a business curriculum, accounting is considered one of the three "number-crunching" topics (along with mathematics/statistics and operations management). The objectives of the accounting course are to 1) Demonstrate an introductory understanding of the rules, concepts and principles that guide accounting practice, 2) Demonstrate a basic understanding of the use of financial statement information and related industry information to make business decisions, and 3) Demonstrate an understanding of the managerial uses of accounting information for internal decision-making.

Design Approaches to Encourage Student Involvement

Five elements were designed into the course to encourage student participation and a feeling of belonging. They are: 1) development of a personal homepage, 2) weekly discussion topics, 3) a course-long collaborative project, 4) a designated area to ask questions of the instructor, and 5) an area for the students to have open-ended, unstructured discussions.

The first task students are asked to perform is to prepare a personal "homepage" within the BlackBoard coursesite. Students are asked to provide information about their work experience, their current position, and why they are taking the course. They are also asked to provide information regarding their educational background and hobbies and interests as well. Finally, they are asked to post a digital photo of themselves. The instructor posted his own personal information as an example, using a very informal style.

Students are expected to master a number of quantitative skills during the course. A number of "homework problems" are assigned to assist the student in this endeavor. The quantitative solutions to these problems are posted on the coursesite. The discussions among the students emphasize what importance the quantitative results have and how management and others use them in decision-making.

Student discussions occur in two parts. First, the student is asked to prepare an individual response to a question and to post their response by Thursday evening. The students are then asked to read the responses by their classmates and to respond a second time—this time by the following Monday evening. Examples of some discussion questions:

- What is the role of accounting in modern society?
- Why is consistency and comparability so important for financial reporting?
- What is the reason for accruals and deferrals in accounting? Assume that you need to present a concise explanation for your superior (who naturally knows little about accounting). Define the terms, describe why they are necessary, and give three examples.
- How does the time value of money relate to either a) your house mortgage, b) your car loan, or c) your car lease?
- Access the annual reports for Compaq, Dell, and Gateway. Describe the differences in the capital structures of these three companies.
- Why doesn't the accounting concept of 'product cost' include all of the costs identifiable with a product?
- What are different ways that costs could be 'assigned' to cost objects?
- Give an example of each of the following that you interact with on a frequent basis: Cost center, Revenue center, Profit center, Investment center

These discussions are the main method of building the community of learners. Over the span of the 15-week course the students get to know each other through the continual interaction. It is possible that they interact more than they would in a face-to-face course.

A major assignment in the course is designed to require the students to collaborate on a financial analysis of a publicly traded company. The project is split into three sections, each lasting approximately 4 weeks. Groups of three to four students are created (to ensure that students would be from all geographical areas rather than concentrated in one area). The workload is also assigned, with one student designated the editor for preparing the report. The editor position is rotated among the students for each section.

An excellent technique used to help students feel less isolated is a discussion area called "Raise your hand—ask the Professor." This is a spot where a student can post queries regarding homework problems and concepts for the instructor. This technique is helpful in two ways. First, the students realize they are not alone—others have the same questions they do. Second, questions are centralized for the instructor so they can be answered once. This helps prevent the course from becoming a burden on the instructor, answering the same questions over and over.

The final component is an open-ended discussion area called "The water-cooler." This is a spot where students (and the instructor) can talk about whatever is on their mind. During the spring semester a lengthy debate over the relative merits of all-inclusive Caribbean resorts stretched over several weeks. Needless to say, this has helped everyone relax in the course.

Student Reaction

In post-course evaluations, many students expressed trepidation prior to taking the on-line course. Numerous students were concerned about the quantitative nature of the course. After the course was completed, most of them expressed satisfaction with the learning environment. As one student commented in an e-mail "…this was my first course in the MBA program, and I really feel like I learned a lot more than I expected to, mainly through the commentaries and the real-life examples posted by others through the discussion board." It is this instructor's opinion that the explicit community building design elements are a major reason for the students' high satisfaction levels with a potentially isolating and intimidating quantitative course.

The Effect of Speech and Pointing Conditions on the Comprehension and Recall Performance in a Multimedia Presentation

Cholyeun Hongpaisanwiwat
Department of Computer Science
Thammasat University, Thailand
Email: chhong@cs.tu.ac.th

Michael Lewis
School of Information Sciences
University of Pittsburgh, PA
Email: mlewis@mail.sis.pitt.edu

Abstract: Forty students from the University of Pittsburgh participated in a study conducted to examine the effects of pointing conditions and voice types in multimedia presentation on comprehension and recall performance. No significant differences were found in comprehension for voice types or pointing conditions. Nonetheless, voice types had an impact to recall performance. The participants viewing the presentation with a human voice had better recall for "pointed out" objects than the participants viewing the presentation with synthetic voice. Although not significant, the pointing condition led to worse recall performance than the no-pointing condition. This may reflect the result of distraction.

Introduction

Multimedia presentation can provide an effective learning environment by utilizing human memory of visual and verbal resources to produce better knowledge transfer. Mayer (2001) has shown that verbal narration accompanying visual information can be simultaneously processed in working memory to help learners digest material. Sweller (1999) has shown that multimedia presentation can make technical material become easily understandable. However, there are few studies of the effects of attentional control or voice type in multimedia presentations.

Instructors frequently point to objects to draw students' attention to those that are crucial elements for a lecture, or to make a referential link. Faraday and Sutcliffe (1997) have shown similar effects for multimedia presentations in which objects to which the subjects' attention was directed by an arrow are better recalled.

The quality of voice used in presenting a multimedia lesson is another important determinant of comprehension. Even though advanced synthetic speech, known as text-to-speech, has been used in many applications such as telephony systems and reading e-mail, a human voice is generally preferred. Recent research has found that while comprehension of synthetic speech was significantly worse than human recorded speech; after people grew accustomed to the synthetic speech, the comprehension performances of both speech conditions became comparable (Lai, Wood, & Considine, 2000). The goal of this study was to examine the joint effects of synthetic and human speech, and a pointing symbol on comprehension and recall performance in multimedia presentation.

Methodology

In an effort to simulate a real-life situation, a finger symbol was used as a pointer. The study was a 2 (voice types: synthetic and human) by 2 (pointers: no-pointer and finger) between-subject design. The dependent variables were comprehension and recall performance of "pointed to" and "non-pointed to" objects.

PowerPoint slides from a conventional computer graphics course were used as the basis for the multimedia presentation. The script of each slide consisted of the instructor's narration and a sequence of locations to which the instructor had directed attention.

Forty University of Pittsburgh students who had never taken a Computer Graphics course were recruited as participants. Upon arrival, participants were told that they would be participating in a multimedia learning environment study. They viewed two sets of slide presentations. The presentations were set to run automatically without any intervention from the students. The participants were required to wear the headphones and were informed that they would be listening to a computer-generated voice for the presentation. When the first presentation stopped, the participants were given tests before proceeding to the second presentation.

Results

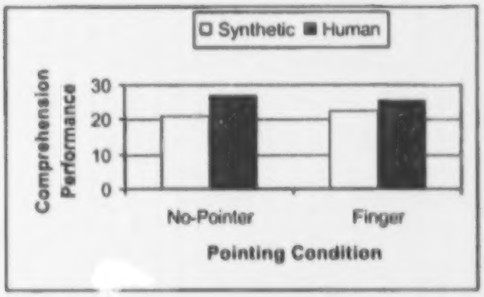

Figure 1: Mean values for comprehension by voice type and pointing condition

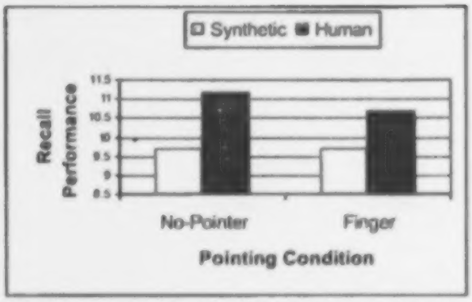

Figure 2: Mean values for recall performance by voice type and pointing condition

The result showed that neither voice type nor pointing had a significant effect on comprehension. Nonetheless, the participants listening to the human voice presentation had marginally better comprehension performance than the participants in synthetic voice condition ($F(1,39)=3.091$, $p=0.087$) as seen in Figure 1. The result also showed that listening to synthetic voice presentation caused poorer recall performance for both "pointed to" and "non-pointed to" objects ($F(1,39)=4.468$, $p < 0.05$). As seen in Figure 2, students viewing the presentation narrated by synthetic voice had poorer recall performance than students who viewed the presentation with human voice. Interestingly, pointing did not affect recall performance. Voice type was found to affect recall performance for "pointed to" objects ($F(1,39)=4.408$, $p <0.05$), but not "non-pointed to" objects. The results also showed no effect of pointing conditions on recall performances for "pointed to" or "non-pointed to" objects. Contrary to expectation, the performance of recall involving "pointed to" objects in the finger conditions were worse than the recall performance in the no-pointing condition ($F(1,39)=3.061$, $p=0.089$).

Discussion

This study did not support the previous findings that synthetic speech led to poorer comprehension than human speech. This is encouraging for multimedia applications because it is more efficient to synthesize speech than to store an exhaustive library of utterances. However, the human speech led to better recall performance than the synthetic voice. This may be because the synthetic voice required participants to pay more attention and spend more cognitive resources for processing audio information than visual information; as a result, the participants poorly recalled visual objects. In other words, this effect may reflect the interference between visual and verbal resources of which one resource demands more processing than the other when a source of information is unclear. In addition, since the content used in this study is somewhat specific in technical areas, the result may not hold across other content areas. Surprisingly, the use of pointing to guide attention led to poorer rather than better recall for the "pointed to" objects. We hypothesize that because the pointer remained visible on the presentation all of the time the pointer and its movements may have distracted the learners. A further study could eliminate this source of distraction by using a pointer which appears only when a referential point is made and is faded out when it is not necessary.

Ocean View and River Run: New Internet Tools For Facilitating Scientific Inquiry

While the science education community values inquiry-based science instruction, implementation at the K-12 level remains illusive. Public school science teachers often site problems with time, supplies and equipment as reasons for not implementing inquiry instruction. However, new Internet based Java Applets provide exciting new opportunities for teachers to implement inquiry into local environmental problems using massive data sets previously not available. These Internet based resources are user friendly, highly interactive and engaging for students at all levels. This session will model the use of two locally developed Java Applets designed to support inquiry instruction as called for in the National Science Education Standards (NRC, 1996).

A Visual Tool to Support Personal Management of Information on WWW

Akiko Inaba and Takanori Yamamoto
ISIR, Osaka University, 8-1 Mihogaoka, Ibaraki, Osaka, 567-0047 Japan
inaba@ai.sanken.osaka-u.ac.jp

Abstract: We have developed a visual tool to support personal management of information on WWW; MyBookMark. The MyBookMark realizes the following; (1) to adopt two-dimensions DMI like graphical depictions of Venn diagrams, in order to provide the overview of the bookmark-holders and simple operations both saving and searching bookmarks, (2) to allow users to save a bookmark in several folders, in order to reduce difficulty to select only one folder for saving it, (3) to provide flexible searching functions using the information about web pages, in order to make easy to find an intended bookmark, and (4) to treat the data of multiple bookmarks, which indicate the same web page, as unified data, in order to reduce confusion. The tool was valued at easy to use, convenience and useful by users

The Problems

When you save a link to a web page as a bookmark into "My Favorite" system, which is embedded in a popular web browser, have you ever had difficulty to decide which folder is suitable for a bookmark? Have you ever had difficulty not finding the bookmark which must have been saved into the system? In a bookmark management system like the My Favorite system, the bookmarks, which indicate the same web page, are often scattered here and there. Does it get confused? Due to the hierarchical structure adopted in such system, these problems are occurred. Do you feel easy to use such systems?
It seems to be difficult to construct a reasonable hierarchical structure to classify web pages. The hierarchical structure will work well in well-structured already-known world, but WWW is increasingly growing and ill-structured world. Moreover, there are so many web pages in different grain sizes; some pages deal with very specific topic, and some pages have a lot of information like an overview. If you save a page which has so many information, you may want to save it into several folders. For searching the bookmark, you will want the system to treat the bookmarks to the same web page as the same bookmark, even if they are in different places. Supposing a tool also offers flexible searching functions, it will be wonderful. Of course, it is also important the tool is easy to use, and its interface is seamless through all functions.

MyBookMark: A Visual Tool to Support Managing Information on WWW

To solve the problems, we have developed a visual tool for managing personally an increasing number of information on WWW; we call the tool "MyBookMark". The MyBookMark will work as a personal meta-database for WWW like the My Favorite system. Fig. 1 shows an example of saved bookmarks and information added to the bookmark. In the figure, there are three windows; (a) is the window of a popular web browser, (b) is the main window of the MyBookMark, and (c) is the window showing information added to a bookmark. The MyBookMark works as plug-in tool for Internet Explorer. Users can start the tool to click a button located in the tool bar of the browser. In the main window, there are several folders to save bookmarks; "HCI", "AI", "CSCL", "conference" and so on are labels for each folder. When the user click one folder (or intersection of several folders) in the window, the tool shows bookmarks which are saved in the folder(s) as a list in the green box; in this example, "E-Learn2002", "AIED2003" and so on are the title of the bookmarks which are saved in the folders "CSCL" and "conference". In (c), there is information added to the bookmark "E-Learn2002". Each bookmark has a title, an

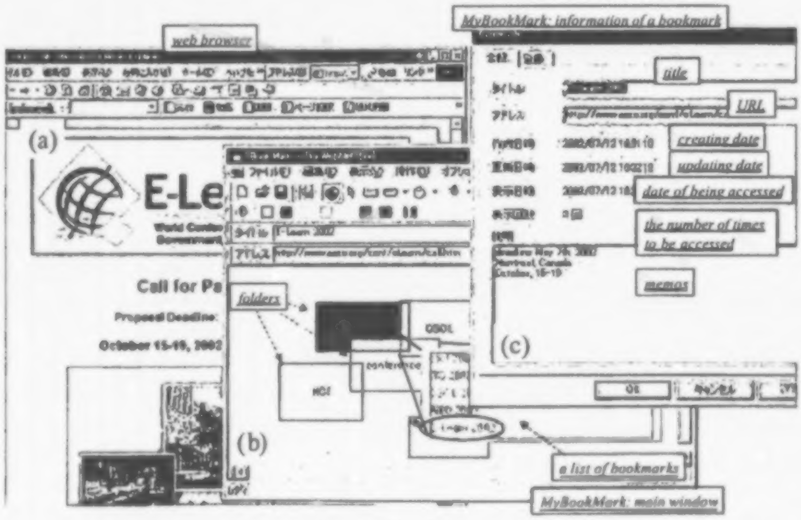

Figure 1: An example of saved bookmarks and information added to the bookmark.

BEST COPY AVAILABLE

URL, creating date, updating date, date of being accessed, the number of times to be accessed, and memos. Users can edit the title and memos, as they like.

The MyBookMark has several advantages as follows;

- *We can know instantaneously what folders are already made to classify bookmarks.*

The MyBookMark has one window in two-dimensions to arrange folders, save bookmarks, and search them. In the window, all folders are the same layer, and we can see the folders all together.

- *We can make, color, resize folders as we like, and arrange them any places in the area of the tool window.*

The MyBookMark has direct manipulation interface. We can make a folder by drawing a rectangle in the tool window. To change color or size of the folder, the window has buttons in its toolbar. We can locate the folders on any place in the window by simply dragging them.

- In the MyBookMark, data of multiple bookmarks, which indicatethe same web page, are treated as a unified data.
- *We can add memos to each bookmark.*

The memos can be used in searching phase mentioned below.

- *We can use flexible searching functions to find intended bookmarks.*

(1) The MyBookMark adopts graphical depictions of Venn diagrams to realize AND searching function. By making an intersection between two folders, users can get the list of bookmarks which are saved both the two folders.

(2) Users can use titles and URLs of saved bookmarks for searching. Moreover, they can use the information, like memos, creating date, and the number of times to be accessed, as searching cues. In the example of fig. 2 (a), the user creates keyword-searching area for memos; the keyword is "Montreal". To make intersection between the keyword-searching area and folders, the user can get bookmarks, which saved in the folders "conference" and "CSCL", and have the keyword in their memos.

(3) A problem with this format is the limitations on the complexity of the expression. For example, a maximum of three query terms can be ANDed together in a standard Venn diagram (see Hertzum & Frokjaer 1996). To solve the problem, we prepare Operators. The Operators have three functions; AND, OR, and NOT. Users can do complex search with the operators (See an example in fig. 2 (b)).

Summary

We have developed a visual tool to support personal management of information on WWW; MyBookMark. The tool realizes the followings; (1) a seamless interface for saving and searching bookmarks by adopting a two-dimensions direct manipulation interface like graphical depictions of Venn diagrams, (2) searching cues added to bookmarks, and (3) flexible searching functions using information about web pages like titles, memos, and URLs. The tool was valued at easy to use, convenience and useful by users in comparison with the My Favorite system.

References

The Formation of Experts in the Handling of the TIC. The Case of the Mexican Librarians.

Maribeth Johnson Díaz
Instituto Mexicano de la Administración del Conocimiento A.C.
México
maribeth.johnson@imac.org.mx

Abstract: The libraries have stopped being simple centers of resources and now are transformed into real information units, in where new forms of communication and information access are promoted as innovating systems are implemented in order to support the education-learning processes. In this context, the Mexican Institute of Knowledge Management along with the Public Libraries Board of the National Council for the Culture and Arts of Mexico are looking forward to create new expert Training Monitors to promote the better use and advantage of the ICT.

Introduction

The fast scientific and technological development during the last years has caused a transformation in the way to think and to communicate between us, lately changes that without doubting have significantly stroke its role that had had within the society in the public libraries. Actually, many of these libraries have stopped being simple centers of resources and now are transformed into real information units, in where new forms of communication and information access are promoted as innovating systems are implemented to support the education-learning processes.

In this context, the Mexican Institute of Knowledge Management along with the Public Libraries Board of the National Council for the Culture and Arts of Mexico are looking forward to create new expert Training Monitors to promote the better use and advantage of the ICT.

The experience which we want to share in this congress is about the first stage of this project. Stage integrated by the implementation of a workshop for the national librarians monitors.

Development of the Workshop

The intensive course was given during two weeks, with a 9 to 5 schedule, in which 20 instructors participated. Is important to mention that this group of monitors is responsible to enable the personnel of the public libraries of all Mexico.

The complete information of the workshop was available through Eduweb-IMAC (the Mexican Institute of Knowledge Management's website). Eduweb-IMAC is an e-learning platform which, through the net, promotes the use of telematics and asynchronous tools of communication and information to create virtual communities and the collaborative learning.

Introduction to Internet and its Main Tools of Communication

During this introductory phase, the participants cleared their doubts about the creation and fundaments of the Internet: At the same time, the participants learned how to open a free e-mail account , which would be constituted as an important communication tool for this course.

The rest of the course contents were integrated in three sections:

I. Introduction to the information society.
II. Information technologies.
III. Information products and services.

The workshop was developed with an intensive participation through the three discussion forums. During the course, the number of contributions grew in amount and quality. The participants shared their own experiences in order to get a feedback.

As a final exercise, they had to recreate the content and activities of their own workshops based in their new achieved know ledges.

The participants proposed to integrate into their programs the following:

- The public library and its new role in the information society
- Development of information skills for the librarians
- Evaluation of electronic resources
- Formation of library users
- Development of a social marketing program for the public libraries

Also, the instructors realize the necessity to count with a basic informatics kit to support their presentations, in order to be congruent with their speech and the used tools.

Conclusions and Recommendations

This workshop woken up different reactions among the assistants. There were some of them who face the possibility of a complete change of the way they taught. Others, recognized themselves like isolated professionals, but with a renewed interest to learn and update themselves; and some others showed their necessity to review the Mexican public libraries goals. However, the constant element, was the massive need to integrate themselves into the new working dynamics in order to develop and consolidate their projects.

As a result of all this, a new virtual community was integrated by all the participants of the workshop. The members must develop personal activities and lead their groups to encourage their communities.

Through the communication tools of the Eduweb-IMAC, as forums, e-mail and chat rooms the members of the community will keep in touch.

Creation of an Institutional Website.

Therefore the National Council for the Culture and Arts of Mexico realize the necessity to create its own website, which must to have three areas: Communication, Information and E-learning.

Communication

This area will be able to improve the communication between the main department's managers with their staff and with the main offices around the country.

Information

The creation of a Information Unit and a Resources Center will be a basic tool to share and exchange information but at the same time it will promote the construction of knowledge and the cooperative work.

E-learning

The integration of an e-learning platform will be helpful to trainee more people in less time by low cost. Through this new perspective, the distance education will become an excellent option encourage the ICT training.

Conclusion

This workshop is the beginning in the long way to transform and integrate the Mexican librarians into the Information Society. However, this first step to create new ICT Training Monitors will be able to reproduces and improve this new paradigm on which the Mexican public libraries are developing.

Successful Strategies: Collaborative Learning for Blended Courses

Claudine Keenan and Arthur Scott – The Graduate Center of Marlboro College

Abstract:

What are the best ways to collaborate in a blended environment that includes both onsite and online components? Instructors at The Graduate Center of Marlboro College have found that combining constructivist and situated learning approaches leads to successful collaborations among their adult students, enrolled in internet-focused master's degree programs. The instructors use role-plays, scenarios, story and case-based learning in both the onsite classroom and online. These situated learning approaches, when combined with constructivist methods such as team projects, virtual mentors, and peer review assignments, allow students of all learning styles and abilities to achieve stronger performance on their portfolio work. This paper will examine all of these approaches as they are applied in these environments, using a variety of synchronous and asynchronous technology tools, including FirstClass Conferencing, Instant Messaging, listservs, and WebBoards, among others.

Developing a Virtual Master of Engineering at UTS: a Case Study

Abstract

This paper comment on the design and development of a completely Online-subject entitled *Managing IT in Engineering (MITE)*. Combined email, web-site and interactive-internet facilities using Blackboard software have been developed to provide an enhanced learning environment. The paper points to ways in which the experiences gained could be used for developing other subjects in a Master of Engineering course.

Keywords

Information Technology, global education, learner-focused education, Internet, life-long learning, reflective practice, engineering management

Introduction

Educational tools using information and communication technologies (ICT) offer flexible, interactive learning environments which educational institutions are using to provide high quality education customised to learner requirements. The needs of the student in the global environment include the fast exchange of information, which can facilitate more rapid learning.

Managing IT in Engineering

- The authors have increased their use of online teaching since early 1999 when they started with a website for online resources of teaching materials that was used in conjunction with traditional face-to-face teaching, and tutorials. The authors noticed that within tutorial groups the use of student teams encouraged students to take a deep approach to their learning. However student collaboration outside tutorials was insignificant, (Madadnia & Koosha, 2000).
- In 2000, the authors extended their use of online environments with a pilot model of a fully online subject with no face-to-face teaching. The flexible learning environment suited off-campus students. The students were mainly mature age, postgraduate with substantial work experiences in a wide range of fields including education, telecommunication, engineering, and management. They demonstrated their skills in management, ICT, and engineering by developing as an assessment task an ideal online subject. In partnership with students, the authors developed a common understanding of the techniques, which were perceived by students to improve student learning.

Guiding the development of the fully online subject was the authors' belief that:

- Students adopt different approaches (deep or surface) to learning, and the approaches adopted are strongly influenced by the teaching and learning design not applied technology (Ramsden, (1992); Prosser & Trigwell, (1999)
- Use of online learning environments can enhance student learning and skill development in research as suggested by Alavi, *et al* (1995); and Ives & Jarvenpaa, (1996).
- The use of teaching strategies such as student learning partnerships
- Can further motivate student participation in activities leading to enhanced learning, understanding, and research capabilities (Madadnia & Koosha (2000) and Madadnia et al (2001a-d).

Significant feature of the development of MITE proved to be the implementation of teaching and learning activities in virtual teams (VT). A VT is used by students for critical discussion with peers and facilitators. Katzenbach & Smith, (1993); Keen, (1990); Jarvenpaa & Ives, (1994); and Gorton & Motwani, (1996) have shown that such activities can lead to increased student satisfaction through enhanced learning and skill development.

The online delivery of MITE proved to be a creative learning environment and open to innovative thinking and suggestions. The web site access statistics indicate the level of involvement of the students. 56 off-campus students accessed different parts of the subject's learning environment 64,892 times (an average of 1160 hits per student). A breakdown of access data indicates that students used the software:

- 35.8% as an information resource to access learning materials (Content Areas),
- 36.7% for synchronised and asynchronised discussions with peers and facilitators (Communication Areas),
- 10% for discussion within their virtual teams (Group Areas), and
- 13.1% for student assignments, home pages, CV, journals and other similar student homework (Student Areas).

Students accessed the site around the clock, seven days a week, throughout the semester.

As part of subject feedback students were asked to compare and rate their preferred technologies to be used in an online Master of Engineering course at UTS. Table 1 provides student perception of a preferred degree delivery approach

Techniques and technologies	Relative score
1. Interactive Learning Environment (Blackboard software)	100
2. Online voice and video (no interaction)	83
3. FTP and bulletin boards	82
4. E-mail	79
5. Block mode delivery and face to face teaching.	67
6. Corresponding (Paper based) course	57
7. CD ROM	40

Table 1. Preferred Degree Delivery Technology

In considering the students' ranking of technology it should be remembered the student were off campus & mature aged. The ranking is also based solely on the students' perception of the ability of each technology to meet their needs. It does not take into account other factors, such as cost or feasibility.

Conclusion

The trend in education is to provide flexible courses, which train, educate, and develop skills. In this paper we have presented evidence of student perception of delivery techniques used at UTS that suggest an interactive Blackboard (UTSonline) type delivery is the best when accompanied with an appropriate learning design, a conclusion supported by Biggs (1999), and many others.

Abstract:

Ever increasing demand for quality learner-focused, lifelong virtual courses necessitates a careful consideration and attention to effectiveness of *assessment techniques"*. This article describes how virtual assessments were developed and evaluated in a completely online subject. The virtual students were involved in development and selection of virtual assessment techniques including online self, peer, and the instructors' assessments. Most students were satisfied with the outcome of virtual assessment.

The authors noticed that learning about significance of virtual assessments could be attained to the satisfaction of more students if sufficient time is spent on introducing the role of virtual assessment in enhanced learning.

It was realised that assessment in virtual environment can enhance student learning and need to be considered in the development of a learner-focused subject.

Keywords

Virtual assessment, IT, elearning, global education, learner focused education, Internet, life-long learning, reflective practice, engineering management,.

Assessing Students

Ever increasing demand for quality learner-focused, lifelong virtual courses necessitates a careful consideration and attention to effectiveness of *"assessment techniques"* (Biggs, 1999). Assessment is fundamentally about helping students to learn and teachers to learn about how best to teach them, (Ramsden, 1998). Assessment is about getting to know our students and the quality of their learning. (Rowntree, 1977).

The University's surveys by Course Monitoring and Improvement System Analysis and Data between 1998-2000 have identified assessment as the top priority area for enhanced learning. The second priority was using virtual tools such as UTSOnline as an additional medium for assessment. At our university, the rollout of e-learning opportunities for students has been rapid, from one pilot subject with 550 students in 1997, to over 500 subjects with 16,000 students in 2001. These opportunities have afforded increased flexibility in time and location of learning for students, and in many cases has also afforded qualitatively different learning experiences. In recognition of these achievements, the e-learning initiative at UTS won an international and a national award in 2000.

The challenge is developing an effective assessment, which would enhance student learning in a virtual environment. Brown and Dove (1991) have highlighted the significance of involving students in peer assessment. The Authors have also developed a distinctive and innovative approach to the integration of e-learning into teaching and learning, and student assessments (Madadnia et al. 2001a-d). The authors' surveys of their virtual students in their two completely online subjects, Managing IT in Engineering (MITE) and Project Management Support Systems (PMSS) have shown that engaging students in the learning assessment has

- Improved student understanding of assessment criteria".
- Reduced strains on the relationship between the assessor and the assessed.

- Improved team working and collaboration between students instead of competition.
- Made assessment a fun rather than a burdensome tedious one-way process with little real learning.
- Generated benefits in students' both enhanced learning by doing, and satisfaction which can justify the time and energy assessments take.
- Assisted students to learn through assessment as an integral part of learning process rather than regarding it as a separate and discrete event.
- Assisted student to consider assessment as a teaching, or skill development activity rather than a testing device, and therefore contributes to the learning process.
- Appreciated the significance of team assessment since teamwork is often the nature of working in any industry.
- Provided opportunities for more people to take part in the assessment process with maximum interchange between learners themselves as well as educators.
- Built trust and confidence in students allowing them to take a risk and feel that they are will be supported if they make a mistake in peer assessment.
- Reassured that the emphasis in assessment is on developing, rather than a simple "right or wrong".

However the authors experiences have indicated some shortcoming in engaging students in assessments such as:

- Students avoided passing judgement on their peers or gave everyone the same "mark". It was difficult to assess virtual team performance in parallel with individual contributions.
- There is no simple formula to solve these kinds of problems. It is against this background, however, that the paper suggested the particular approach towards more learner involvement in the assessment.

Abstract

Online education is receiving increasing attention from community and government in Australia. The authors have initiated the development of two subjects completely online. The subjects are delivered via UTSOnline (or Blackboard), a learning management software, which provides a range of tools to assemble and manage e-learning resources. This paper presents the authors' reflections on their experiences and concludes that e-learning can be effective as a sole delivery strategy as well as a complimentary approach to face to face teaching.

Keywords

IT, e-learning, online education, learner-focused education, Internet, reflective practice, engineering management

Introduction

There have been significant development activities in the area of online-education using multimedia and web based interactive learning modules in science and engineering. Online education employs information and communication technologies to engage students in interactive learning and assessment activities, both vitally important aspects of teaching as outlined by Kadiyala et al (1998). Research shows that student acceptance and usage of educational multimedia is high and off-campus students undertake activities related to their study when the benefits are well communicated to them (Madadnia et al., 2001a - d). However, some academics consider that too much effort is required to use the Internet as a teaching and learning environment. (Reuther & Meyer, 1997).

Authors' Views

Managing IT in Engineering (MITE) and Project Management Support Systems (PMSS) are two completely online subjects, which the authors jointly teach. The subjects are offered to on-campus, off-campus and off shore students.

The online environment is perceived by academics to fall into three categories namely *delivery*, *economic*, and *communication* (Reuther & Meyer, 1997). The main outcome of the first two perceptions is a "load up the existing materials" approach. These perceptions see online teaching as merely a delivery mechanism. The authors believe the real value of online delivery is obtained by embracing the capacity of the medium to enhance communication. Thus the main task of academic staff is not to provide the subject content but to design the teaching and learning activities that engage the students and lead to deep learning and development of desired student attributes and learning outcome.

The authors' two online subjects involve a range of activities to achieve these goals including:

- Establishing virtual teams and confidential team discussion areas
- Online quizzes with automated grading for self evaluation
- Discussion topics on chat boards
- Frequent monitoring of students' work, posting "seeding questions", encouraging continuous individual participation and collaboration.
- Online tutorials in real time

The authors' personal experience, based on subjective evidence suggests that students do engage more with the material and in more critical ways through undertaking these activities. We are confident that an appropriately designed virtual learning environment can provide the same or a greater level of enhanced learning as a well designed face to face learning environment. In the authors' opinion the importance of developing critical learning can not be overstated. Electronic information on the web has none of the traditional safeguards of printed works that offer some security and confidence about origin and validity. The growth of the web means that students of the future must be much more media literate and able to use judgement and analytical skills to interpret and understand the relevance and possible bias of enormous quantities of readily accessible information.

An advantage offered by online delivery is the ease of communication across cities and national boundaries. The ability to establish teams of students from varying locations and culture to undertake group activities is considered an important benefit of the use of the technology.

In short term, the authors believe UTS is moving towards being more of a mixed-mode institution where a combination of face-to-face and online teaching will result in students attendance on campus being less than at present. Our experience of completely online delivery suggests that e-learning offers a tool to enhance face to face courses whilst providing students with greater flexibility in both time and place of study.

Conclusion

The authors believe that the best way forward for the development of e-learning is for universities to embrace a mixed mode approach. There are courses and faculties that may well be readily adapted to an e-learning environment and may go completely online. However, the use of e-learning as a tool to enhance face to face teaching appears to offer benefits for every subject and course irrespective of discipline.

In the future the authors see their roles as educators to involve supporting students in understanding their educational needs, working with them to select suitable online/traditional/external/internal resources and courses, and then working with them to integrate these into a cohesive whole. A shared responsibility by student and teacher for all aspects of the learning experience will need to be understood by students.

RXK141@PSU.EDU

The paper will summarize my findings on teachers' conceptions of the nature, role and purpose of assessment, and factors that influence the integration of different dimensions of assessment. The research participants are in-service teachers enrolled in the "Teacher as Inquirer" course in a graduate level teacher-leadership program at an institution of higher education. The content of the course focused on the following four dimensions of assessment: 1) *policy dimension* (how state and federal policies affect testing and assessment by encouraging and requiring it, and by regulating the use of educational tests and information based on them); 2) *measurement dimension* (the reliability and validity of content, measures of assessment, and grading policies and their social consequences); 3) *curricular and instructional* dimension (alignment of assessment with content, state and national standards, benchmarks, and performance assessment tasks); and 4) *equity dimension* (appropriate accommodation for the effect of a disability or of limited English proficiency on subject matter). Teachers actively engaged in inquiry on what would constitute "strong" assessment practices, that is, practices that integrate the four assessment dimensions. In both face-to-face and on-line discussions, teachers were asked to consider the following questions: To what extent their school wide assessment practices reflect each of the four dimensions of assessment? To what extent their school's assessment practices have changed in relation to the teaching of standards? How can teachers use assessment data to make well-informed, school-specific instructional decisions? What are the impediments?

Each participant identified an assessment problem of school wide importance and implemented a solution at the building/school/district level. Using a Reflective Action Planning Model (see Frost et. al., 2000), teachers outlined a detailed plan of action integrating each of the four dimensions of assessment. The action plan included each of the following steps (Frost et. al., 2000): *Collaboration and consultation* with peers and administrators in school, *systematic inquiry* into assessment issues (data gathering, analyzing, evaluating, and discussing), *professional learning* (mastering new skills, staff training, and developing personal understanding of assessment), and *documenting the process* (electronic portfolio, collecting evidence). Course participants prepared a portfolio documenting their work, which included critical narrative to describe their experiences with data driven inquiry practices. ANGEL, a web-based course management system, enabled course participants to be involved in numerous threaded on-line discussions. ANGEL's collaborative tools facilitated argumentation, persuasion and consensus building around the purpose and function of assessment. Using constant comparison method, data was analyzed to assess teachers' conceptualizations of "strong" and "weak" assessment practices and influence factors.

Professional Development for Mentoring Interns and Teaching English Language Learning Students in the Mainstream Classrooms through the Use of a Website

Over the past 10 years, the English Language Learning (ELL) student population has grown dramatically, particularly as compared with the relatively static pattern of total school enrollment. Recent estimates by the National Clearinghouse for English Language Acquisition & Language Instruction Educational Programs indicate that the number of ELL students has increased by 104% over the past ten years, more than any other group of students in the U.S. today. During that same period, by comparison, the growth in enrollment of children from English-speaking homes has been relatively flat, increasing by only 13.6 percent (NCBE, 1999). "Diversity has thus become the norm rather than the exception for U.S. classrooms." These demographic trends make it essential to consider the needs of these students at all levels of our educational system.

To address these demographic changes, the National Council for the Accreditation of Teacher Education (NCATE) devotes its fourth standard to diversity and in particular to the importance of teacher education programs providing "extensive and substantive" field experiences that "help candidates confront issues of diversity that affect teaching and student learning and develop strategies for improving student learning and candidates' effectiveness as teachers" (National Council for the Accreditation of Teacher Education, 2001, p.31). Cooperating teachers at school sites function as mentors and supervisors of teacher interns and beginning teachers (O'Dell & Huling, 2000). Despite their influence on the intern's growth in teaching, the cooperating teacher receives very little sustained, job-embedded professional development (Silva, D. & Dana, N.F. 2001; O'Dell & Huling, 2000; Sergiovanni & Starratt, 1998). Given the influence teacher interns' field experiences have on their teaching, universities concerned with providing a teacher work force versed in working with diverse learners must attend to cooperating teachers' professional development needs regarding such learners.

Preparing All Administrators, Teachers, and Counselors to work with linguistically and culturally diverse students (PAACT), a project of The George Washington University's Graduate School of Education and Human Development (GSEHD), has made developing cooperating teachers expertise in working with ELL students a primary project objective through its "Mainstream Cooperating Teacher Development" initiative. This three-year initiative is one of several that brings faculty expertise to bear on the reforms universities must undertake if they are going to prepare mainstream education personnel to work with diverse learners. The Mainstream Cooperating Teacher Intern Development Project directed by Dr. Patricia Tate, Assistant Professor of Elementary Education and Director of the Office of Laboratory Experiences (OLE), develops the potential of mainstream cooperating teachers to mentor interns to work with English Language Learning (ELL) students. The goal of this study is to develop improved support structures for cooperating teachers through technology and through professional development.

During the first year of the project, data was collected from a select group of teachers who attended either one half-day pilot test session or one of two full-day focus group sessions. Sixteen cooperating teachers who also had experience in working with ELL students in subject matter classrooms participated in the study. The focus groups provided insights into the multiple challenges facing mainstream cooperating teachers.

Cooperating teachers offered recommendations for the development of a web-based support system to help them address the challenges they had expressed in the areas of working with ELL students and mentoring interns. They recommended a site that offers information and resources as well as opportunities for interaction with other cooperating teachers and with interns. They expressed a need for examples from other mainstream teachers of their experiences in working with ELL students and what they learned from those experiences. They also recommended that suggestions for communicating with ELL students' parents and for conducting parent-teacher conferences be available. The participants expressed the need for information about different cultures, including information on educational systems in different countries and community resources that could support them in their cross-cultural work with ELL students and parents.

Furthermore, the participants recommended that the mentoring portion of the site should include current terminology, methodologies and curriculum used at the university, and the university's expectations of and evaluation criteria for interns. The site should assist interns by including templates for their evaluation, a timeline of assignments, and a current listing of web-based resources containing curricula and lesson plans organized by grade level and/or subject area. Finally, the focus group participants recommended that the interactive portion of the site provide opportunities to post questions and concerns and allow for the discussion amongst cooperating teachers, interns, and university faculty.

As a result of these focus groups, a website for cooperating teachers has been developed allowing for inquiry into and reflection on the various roles of the cooperating teacher in mentoring interns, including the role they play in providing constructive opportunities for interns to work with ELL students in mainstream settings. Staff from PAACT and OLE have used the cooperating teachers' major challenges as organizational categories for the site. Thus, "Developing Relationships with Families," and "Building Relationships with Interns" are two areas of the site clients may visit to obtain resources. The site is accessible at: http://www.gwu.edu/~cooptchr

This website was developed by using the "Dreamweaver" program and also incorporates media such as video clips which provide information about the website's content. As defined by Carr (2001), on-line learning is a reciprocal process of meaning-making within a community of Internet users committed to increasing their knowledge and furthering their understanding of a particular subject area, topic or theme through accessing information, entering into collaborative investigations, participating in synchronous on-line chat, and contributing to bulletin board discussions (Carr, 2001). At the heart of on-line learning is the assumption that knowledge is not a given but is constructed. Moreover, adults have myriad life experiences that can (and should) be used as a resource for learning (Knowles, 1984). In addition, the use of the Internet in training involves shared learning and professional collaboration as the core functions. This is why cooperative teachers will be confronted with a website that is in the process of development. What it becomes is not pre-ordained but rather a consequence of the insights, learning, discussions, material contributed by the cooperating teachers, interns, faculty and other interested citizens.

Tony Carr supports the use of the World Wide Web to extend and augment the face-to-face training.

Disadvantages of training teachers using a website are as follows:

- Participants require computers with Internet access.
- Being on-line is expensive particularly if the participant has a slow modem, processor or insufficient RAM.
- On-line learning can be alienating.

On the other hand, there are a number of benefits that training teachers using a website can provide:

- The removal of geographical and time constraints.
- Demonstration that knowledge construction and meaning making are almost invariably collaborative in nature.
- An opportunity to test and refine theory, perceptions, material within a broader community.
- The utter destruction of the fallacy that knowledge and, therefore, power is invested in one individual or group of individuals.
- An opportunity for individuals, educators or non-educators, to increase their knowledge and furthering their understanding.
- An extensive listing of resources where information can be found, as well as opportunities for interaction with other teachers and interns.
- Opportunities to post questions and concerns and allow for discussion among teachers, interns, and faculty.

In addressing whether computer-based instructional technology is effective, research has found efficacy, however, any more replicative and exploratory studies are needed. Esther (1995) in reviewing literature on computer assisted instruction (CAI) and learning style, found that CAI

BEST COPY AVAILABLE

can significantly improve the learner's achievement and attitudes while decreasing necessary instructional times. Kulik and Kulik (1991) in examining a large number of studies found that computer-based tutorials produce improvements in learning outcomes on an average of 20 percent greater than average. Simulation, interactive video, hypertext programs, bulletin boards and networks have also been found to enhancing learning (Cronin and Cronin, 1992; Khali and Shashaani, 1994; Kulik, Kulik and Schwab, 1986; Schlecter, Bessemer and Kolosh, 1992). In summary, there is a good research for demonstrating that instructional technology often optimizes learning. Milheim and Martin (1991) in studying learner control motivation, attribution and informational processing theory, identify learner control as an important variable in developing the pedagogy/androgogy of websites. It is beneficial to generally maximize learner control as it increases relevance to learning, expectations for success and general satisfaction contributing to heightened motivation. (Keller, 1987). Using computer-based instructional technology helps learners focus on the "needto-know", and provides opportunities to jump to the "like-to-know"(WAVE). Motivation is never a problem when simulations and labs offer learning on "as needed" basis (WAVE, 1997).

In the spring of 2002, the focus group cooperating teachers were invited to preview, critique, and provide feedback for the developing website. Cooperating teachers gave the following advice concerning the website. They suggested that the font should be bigger, bullets should be added and the length of the text should not be too long. In general, they were excited about the outcome of the website and felt empowered to implement this vast content in their daily practice of teaching and supervising interns. We, in collaboration with our cooperating teachers, are continuously updating this website and are excited to continue and improve our work in the future.

The approach for automatic generation, comparison, and classification of control problems is discussed. Any problem is considered as uniform task to transform a given state from a set of initial states into a state from a set of target states. The problems differ merely in the development of their solving processes. For automatic problem generation (APG) is used a method "generato-and-test computations". For the automation of the processes of analysis of the solution of control problems and generation of new problems the research prototype of the tracer interpreter is developed. The pilot tasks formed by APG are recommended by experts to train pilots of the aviation of the Pacific Navy of Russia.

Key words: **Pilot Training, Problem Comparison/Classification/ Generation, Production Systems.**

1 Introduction

In paper [2] we described the model of studying problem, which can be used to compare, to classify and to generate the uniform problems, solved by general method.

Let us consider the modification of this model in the case of the exercises (actions), made by operators, for instance on a flight simulator, to control of moving objects or technological cycles in accordance with the clear set of instructions.

2. Classifications and Generation of Problems for Pilots

The APG (automatic problem generator) for generating of problems with assigned characteristics and with taking into account the specific features of the use of a flight simulator in the process of instruction, we checked on an example of teaching pilots of approach landing. The trainee has the following task: to fly an aircraft following the assigned path in the multidimensional space (by number of parameters specifying the state under observation), considerable deviations from which are eliminated in accordance with the rules to be studied. It is assumed that the necessary preliminary knowledge are already mastered by the pilot up to the moment of the beginning of instruction.

In the example the predetermined trajectory is an extended-space landing option, the initial state is the aircraft's bypass over the take-off/landing strip, and the final state is a moment of landing at the beginning of take-off/landing strip. The process of fulfilling of the piloting problem of approach landing may be in the following basic states: the turn, the horizontal flight, the descent, the holding an outer/inner locator, ready/not ready to landing. Furthermore, additional states, which are the result of external actions and errors of the pilot, are possible. The process of fulfilling the exercise falls into the final state, if up to the moment of passage into the state deviations of current values of state variables from required values are less than allowable. In this case the problem is considered as fulfilled. The allowable actions of the trainee are as following: reduction/increase in altitude/speed of flight, corrective turn to the left/right, reduction/increase of roll to the left/right, the continuation of the turn of the horizontal flight.

The actions of the trainee are modeled by indeterminate production system contained 59 rules. For the automation of the processes of the analysis of the solution of problems, their classification, comparison, and generation of new problems the research prototype of the tracer interpreter is developed. The interpreter of production rules is simulated on the base of the interpreter of Prolog. For the problem generation the generator of the parameter and the tracer interpreter as a solver are used. If assigned and calculated classes on some step are the same, then the generated problem is approved, otherwise the additional cycle of the generation of the parameters and checking occurs.

4 Conclusions

As a result of application of the considered approach to generate problems of control for pilots it was possible:

- to formulate various classes of tasks with the given properties which take into account a specific character of training on a simulator, to exactly determine preliminary knowledge and skills of the trainee required to master a new procedure;?
- to form as a result of classifications the sets of tasks which ensure a cover of the subject area, to ensure their greater variety and step-by-step complication;?
- to ensure a reliable registration of wrong actions of the trainees, an impartial assessment of the level of flying skill.

The tasks received with the help of APG are recommended by experts to train pilots of the aviation of the Pacific Navy of Russia

The IQ FORM research project develops a supportive learning environment for the Virtual University of Finland, a consortium of all the Finnish universities. The IQ FORM gives information about learner's qualities e.g. learners' strength profiles and motivational structures as well as social navigation during their virtual studies. The objective of the presentation is to demonstrate shortly the IQ FORM tools and discuss the research connected to the IQ FORM project. (http://www.edu.helsinki.fi/iqform/). The tools developed are 1. IQ FORM - intelligent questionnaire for self-assessment, 2. Tutoring package 3. Learning diary.

This particular study explores what is meant by mediation in virtual learning environments. The theory of mediated learning experience of Reuven Feuerstein is the background for this research. Mediation can be broadly defined as an intervention method intended to improve the adaptability and flexibility of learners in new learning situations. In a netbased learning environment, the learner is usually the one who has to do the adaptive work. Can learning skills be modified through mediation in technology based learning environments?

The purpose of the research is to find out, if the IQ-FORM has mediative elements, which support students. Feuerstein's five first criteria of mediation (1) Intentionality and reciprocity, (2) transcendence, (3) mediation of meaning, (4) mediation of feelings of competency and (5) mediation of regulation and control behaviour are studied. Research data is collected through thematic interviews of students using the IQ-FORM at the Northern Carelia Polytecnic and the University of Helsinki. The initial results of the student experiences are going to be presented in Montreal.

Alternative Communication Methods in Online Settings: A Study of Demands and Effects

Matthew Leavitt, J. Michael Spector, Peter Gray, Noorazah Reduan & Radha Ganesan
Instructional Design, Development & Evaluation
Syracuse University, Syracuse, NY USA
mcleavit@syr.edu

Abstract: This study focused on the effects of communication in online settings (synchronous, asynchronous, and e-mail) on learning outcomes, time on task, and resources. Three university courses were studied; each at a different level (graduate, undergraduate-upper/lower division), and each conducted entirely on-line using Blackboard or WebCT course management software. Activity logs and the course management software were used to collect data from students, faculty, and staff regarding the time spent on-line and off-line communicating and completing various other tasks. Students were asked before and after the online course how the course would/did compare to a traditional classroom course. Areas included topics such as difficulty, time spent, enjoyment, convenience, pace, and workload. Preliminary findings indicate: no significant difference in learning outcomes; time demands vary significantly with the primary method of communication; considerable differences in on-line time on task for students within each course; substantially more instructor time required than in traditional courses.

Online learning is relatively new, but it is rapidly growing both in and outside university settings (Rosenberg 2001; Spector & Anderson 2000). Many important questions remain unanswered or unexplored, including which approaches and methods are optimal in terms of cost and learning effectiveness in various settings and situations. Relevant differences in variables likely to effect our understanding of what works best and why with regard to online learning include the following (Branch & Fitzgerald 2001; Kearsley 2000; Pea 2000; Salmon 2000):

1. Differences in audiences (on-campus undergraduate and graduate students, off-campus adult learners, students and teachers in remote schools, etc.);
2. Differences in learning situations (home access via modem, high-speed access on campus and in the workplace, no web access, time constraints, etc.);
3. Differences in course setting/approach (web support for campus courses, completely online courses for remote learners, residency and distance learning combined, etc.);
4. Differences in communication methods (asynchronous threaded discussions, synchronous forums, video-conferencing, etc.);
5. Differences in instructional strategies (structured learning activities, discovery learning, problem-based learning, etc.);
6. Differences in learning goals (conceptual knowledge, understanding complex relationships, procedural training, etc.); and
7. Differences in tools and technologies (web-course management systems, courseware authoring tools, interactive simulations, etc.).

It is unlikely that any single approach, method, tool, or perspective will be appropriate for all audiences, situations, and desired outcomes. Taxonomies around these seven dimensions can be constructed to guide the instructional decision making process, but important information in many cells is missing, including how cost effective a particular technology or approach is in achieving a desired goal with a particular community of learners.

The focus of this Mellon Foundation Cost-Effective Use of Technology in Teaching study was on the cost effectiveness of online courses, especially with regard to the communication dimension. Relevant data included resource requirements (including non-recurring costs of system setup as well as the recurring costs of staff support); time burdens placed on course designers, instructors, and students; as well as overall learning outcomes. Faculty from the Syracuse University School of Education, The College of Arts and Sciences, and the Maxwell School collaborated in this study. The three courses involved were: Instructional Design (graduate level), Geography of Latin America (upper division undergraduate level), and World Religions (lower division undergraduate level).

The data collection effort was designed to create the possibility of suggesting that within the context of a particular course and learning activity that a particular e-collaboration technique was more or less effective or more or less burdensome. Data were collected for at least two online offerings of each course. In the Instructional Design case, data was also collected for a classroom-based counterpart course. The three e-collaboration techniques most commonly used at Syracuse University are:

1. Collaboration only with a tutor/teacher via asynchronous means (minimal e-collaboration via email);
2. Asynchronous threaded discussions with topics posted (modest e-collaboration); and
3. Synchronous forum groups with semi-structured small group assignments and goals (more elaborate e-collaboration).

All three courses studied utilized modest to elaborate e-collaboration techniques. Each course maintained an asynchronous course discussion board, which was the principle communication technique for the World Religions course. All three courses also involved intensive email exchanges and chat sessions at least twice during the semester, places at points in each course that most naturally corresponded with course activities (e.g., chat sessions for project work, reports, and exam preparation).

Overall findings suggest no significant difference in terms of learning outcomes between the classroom-based and online version of the Instructional Design course, although there were significant differences in terms of instructor time demands (higher for the online course); students in the online setting perceived greater time demands as well. Instructors in all of the online courses reported significantly increased time demands compared with their classroom-based experiences. Instructor reports of the quality of student work and course grades suggest no significant differences in terms of learning outcomes, although all instructors reported that the threaded discussions seemed to be generally better than classroom discussions.

Students reported that taking an online course was more convenient than taking a classroom course. Several of the participating students were able to participate from remote locations across the country and the world. In many other respects, students feel that their experience closely parallels their expectation for an online course. Their experience found only slight or modest variation from the demands of a traditional classroom course. Exceptions appear to be idiosyncratic to the course or student, and may be a reflection of individual course demands, student expectations, and professor expectations.

Using Multi-Media Technology to Teach Foundational Courses in Western Civilization

A demo/Poster Session Proposal for the E-Learn Conference, October 15-19, 2002, Montreal, Canada

By David Walter Leinweber, Ph.D.
Associate Professor of History
Oxford College of Emory University

Abstract

Teaching foundational surveys in Western Civilization at Oxford College of Emory University has afforded me the opportunity to create an extensive library of multi-media materials to aid in classroom learning. I would like to conduct a poster/demo session at the E-Learn Conference in Montreal in which I could display some of these course materials for Conference participants. These materials would include: multi-media presentations setting thematically organized art works to correspondingly appropriate music; a color, glossy printed book of my PowerPoint lectures from my foundational survey course, *Western Civilization through the Reformation*; a Coursebook used by students, based on my PowerPoint lectures/presentations; a video I made on King David, in conjunction with the Teaching, Learning, and Technology Institute of Oxford College of Emory University; course syllabi; student journals; student papers; examinations; student feedback.

Proposal

I would like to sponsor a poster/demo session at this Fall's E-Learn Conference in Montreal, Quebec. This session would display various course multi-media course materials I have successfully employed in my Western Civilization courses at Oxford College of Emory University. In this course, I converted my "yellowed-notes" history lectures into PowerPoint presentations that integrated all the maps, art, quotations, architecture, and topical points of the old lectures into a much more precise, efficient, and discrete format.

A a primary item, the poster/demo session would show the nucleus of my History 101: Western Civilization through the Reformation course: the PowerPoint lectures, and the accompany Coursebook that students purchase for use throughout the semester. I have prepared a glossy, color printed textbook to display these lectures (250 pages). This would be a primary item in my proposed poster/demo session. I have a printed, "handout" version of the PowerPoint lectures that students purchase from the College bookstore. The PowerPoint "Handout" printing mode provides space for students to take notes as they follow along with the PowerPoint lectures. The Coursebook to accompany the PowerPoint lectures has made the course run much more smoothly than in the old days of chalkboards. Students can follow lectures with clear major points delineated, as well as any selected quotations drawn from literary sources, and art, architecture, and maps. Moreover, students can read the Coursebook as a course text, and also see precisely where future lectures will go. This helps them to read the corresponding traditional history textbook – Harrison, Sullivan, and Sherman's *A Short History of Western Civilization* – more intelligently.

Second, I would show, from my laptop and a digital projector, multi-media presentations I have incorporated into the course. Each running about five minutes, these multi-media presentations were also prepared on PowerPoint. They add an important flavor to the course. These multi-media presentations incorporate hundreds of classic art, architecture, and portrait images into thematically organized presentations, set to appropriate music. Some of the presentations topics include "The Virgin Mary," set to Schubert's "Ave Maria;" "The Nativity," set to "For Unto Us a Child is Born," from Handel's *Messiah*; Scenes from Dante's Inferno, set to Faure's "Requiem;" "Tragic Suicides of Classical Literature, " set to "Dido's Lament," from Henry Purcell's 1697 baroque opera *Dido and Aeneas*; "The Islamic World," set to sufi chanting of the Koran; and a beautiful, bittersweet presentation on Judaism, set to the "Hativka." I also have occasionally employed more current music, including a presentation on Barbarian Europe set to Led Zeppelin's "Battle of Evermore," and a presentation on romantic images of the "East," set to Led Zeppelin's "Kashmir." Students have almost universally enjoyed these presentations, finding them a welcome break from my lectures (hmmm). Also, I showed several of these presentations at a faculty development at Oxford College of Emory University during the academic year of 2000-2001.

Third, I would show a video/DV I made while a participant in the Teaching, Learning, and Technology Institute at Oxford College of Emory University. This video is on the "Mythic King," King David from the Bible. "Mythic Kings" was also a special topics course I taught this past Spring semester, 2002, here at Oxford College. It was done using Final Cut Pro, on a Mac. The Mythic Kings video fused the commentaries and perspectives I brought to the table from my own study of history, with the extensive collection of images and sounds I had compiled. It shows how the history of a ancient near eastern king – and an arguably obscure one in a purely historical sense – became one of the more enduring figures in western literature, art, and music.

The video also served as a demo for student projects in the Mythic Kings course. Students were able to see my vision of a multi-media essay, in which traditional essay writing blended in with the powerful possibilities of computer technology. Students were invited to make a video, though some choose the less arduous task of compiling major multi-media presentations, using PowerPoint technology. The approach also worked well with student papers, many of which used desktop publishing and graphic images to take their papers a step beyond the basic, printed-text college term-paper. The King David video was also shown to a faculty development session here at Oxford College of Emory University in February, 2002, where it was very well-received.

The poster/demo session would also include course syllabi, examinations, student journals, and student feedback, available for perusal by conferees at their leisure. Students write in journals subsequent to each class. The journal assignment specifically suggests that students not only reinforce the content of each class session, but also thoughtfully address larger issues raised by the art, architecture, music, and literature made accessible by the multi-media format. The journal entries must be at least 250 words, and can be hand-written.

Also, examination formats can also dovetail onto the integrated media made available by PowerPoint lectures. While students do take two fairly traditional multiple choice examinations, and write a major term paper, essay examinations can also ask students to reflect on the thematic historical issues and problems illustrated by art, architecture, music, librettos, oratorios, and literary texts. I often show a multi-media presentation to students as a part of the final, and ask them to write several paragraphs highlighting themes raised in it. For example, the final examination for this past semester, Spring, 2002, concluded by showing a PowerPoint presentation on the Islamic World, as well as one on "barbarian" Europe. Students were then asked to compare and contrast the presentations, discussing the important themes they raised with regards to Western Civilization. This affords them the opportunity to discuss larger issues and problems, while still being grounded in the course's factual content. In this regard, students responding to such an essay question typically highlight religion, geography, political systems, and thought as major topical points.

The multi-media course materials I have prepared for my History 101 course have been very positive additions to my teaching of Western Civilization. Students have invariably commented positively about them on student evaluations. I would truly appreciate the opportunity to share my positive experiences using technology in the college-level classroom with other professionals and colleagues.

I thank the E-Learn organizers for considering this proposal.

A WYSIWYG editor for a web writing course

Abstract

This paper describes a what-you-see-is-what-you-get (WYSIWYG) editor to support a web-enhanced writing class. The primary objectives of this editor is to enable teachers to mark assignments submitted by the students on line and to facilitate students' peer review of each other's work. This is a module supplementing an existing writing platform for students of English as a foreign language. The original application provided discussion forums and allowed the construction of electronic portfolios that integrated students' drafts, final papers, and teacher's corrections. For the online correction component, we have used the IFRAME label and DHTML scripts to construct an editor that supports WYSIWYG functions to allow teachers and fellow students to offer comments, to add standard correction symbols, and to mark the erroneous sections of students' papers using only the web browser.

Introduction

We developed the online writing platform and added the online marking component in response to a need to mark a large number of papers submitted by students in a web-enhanced English as a foreign language (EFL) writing course. It is not uncommon for an EFL teacher in Asia to be facing classes of 30 to 50 students. In the process of correcting papers, most teachers use standard correction symbols, make strike-through lines, underline words or phrases, highlight words or add comments between the lines. These tasks can be easily done with a pen on paper or with a word processor, but impossible to do with using a web browser. The text areas in the forms of HTML documents do not support styles, let alone other functions such as auto numbering or word counting. It is possible for teachers to use word processing programs like Microsoft Word to mark the sections or sentences needing correction with different colors. In order to do this, the teachers must download them, correct them, and upload them again. For the teacher, this three-step procedure is inconvenient and opens up the possibility of losing papers or uploading them to the wrong places. It is also inconvenient for the student author and his or her peers to view each other's works. Embedding the necessary functions into a web editor so that teachers can correct papers and students can view the papers on line would facilitate the review and correction of the assignments and increase the efficiency of the online writingplatform.

Technical aspects of the system

The objective of our project was to design an online editor embedded in an Internet browser. This would be part of an online writing platform for students to submit papers for evaluation and discussion by peers and teachers. Standard forms in HTML do not support styles in the text areas. We incorporated a self-contained WYSIWYG HTML editor in the web page with editing capabilities. Using this editor, no additional plug-ins are required. The teacher and peer editors can control their output using HTML forms, correct students' papers using styles, colors, strike-through lines, underlines and give comments. The actual program is implemented using Apache (version 1.3 or higher) as a Web server, MySQL as the database server running on a FreeBSD operating system machine, PHP as the programming language on the server side, and DHTML/HTML/JavaScript to provide the user interface on the client side. The system was tested using MSIE 5.0-6.0. It does not work in Netscape because Netscape does not support the part of DHTML that this module needs.

Formative Evaluation

A formative evaluation of the writing platform in conjunction with the WYSIWYG editor shows that they indeed can help meet the pedagogical goals of process-oriented communicative writing. The instructor of the course found the system to be an invaluable tool that supported the teaching strategies used in her EFL writing class and allowed for the construction of electronic portfolios. The writing platform and WYSIWYG editor made possible the smooth completion of resource sharing, process writing and peer-reviewing activities, all essential components of the curriculum. It drastically reduced the amount of time the teacher spent on menial paper-shuffling and record-keeping tasks. One drawback of the system is that it requires the instructor to be constantly online when marking the papers.

48 college students enrolled in a required college freshman writing course at a college in Taiwan participated in formative evaluation of the system. They were all English majors and place at the intermediate or high intermediate level of language ability. During the academic year starting in fall 2001, they used the system to complete all their writing assignments. The students wrote narrative and descriptive paragraphs, comparison/contrast essays, definition essays, and argumentative essays. They also discussed their classmates' work asynchronously and peer edited each other's papers.

Small group interviews revealed that all students believe the system to be reliable and easy to use. Even though not all the students prefer writing with a computer to writing with paper and pen, they all admit that computers facilitated the processes of editing and revising. The best part of the system in their view was being able to check online which papers they had submitted and which they had not. Peer editing had been a new activity they all approached with apprehension and reluctance. However, after the teacher's repeated modeling of the behavior and the thinking process involved, the students' gained confidence and increasingly appreciated its value in their learning process.

Networked Portfolio System and Students' Learning Effect

Eric Zhi-Feng Liu
Dept. of Information Management
Ming Hsin University of Science and Technology
Taiwan
totem@mis.mhit.edu.tw

Abstract: Portfolio-assessment is a systematic method for collecting and commenting on samples of work submitted by students. Moreover, these samples of collected work are able to display or explain in greater depth of the learning processes followed by a particular student. Peer-assessment has suitable reliability and validity, enhances a student's high level thinking abilities and motivation to learn, and this makes it an excellent assessment strategy by which to evaluate adults. This system incorporates two distinct types of function; one focuses on peer-assessment, the other involves the design of portfolio-assessment (included self-assessment and portfolio). Author would demonstrate the learning curves of different assessment strategies of students, students' most favorite type of work and some limitations of this study.

Introduction

System developed in this study is based on the concept of portfolio- and peer-assessment (Liu 1999), and aims to apply these educational learning strategies to science education. It is hoped that the use of Internet would allow us to overcome the obstacles of location and time. In this way, interactions outside the classroom is richer and deeper, and therefore is geared more towards helping students' learning.

Those teachers who wish to make a break with the assessments provided by traditional "quantitative" marking or pen and paper tests might consider the use of portfolio-assessment. By their nature such portfolio-assessment is a form of authentic assessment, and has long been widely used in the fields of art and writing (Paris & Ayres 1994). The possibility of using portfolio-assessment in education is a recent trend of instructional and learning strategy. The purpose of a portfolio-assessment is to record and bring together in a targeted way evidence of a student's learning process, insights, abstracts, performances, work and self reflections, and to submit these to assess the gains and progressions of the learning of students. As such, this should be regarded as a formative assessment in each learning stage and a summative assessment in a summary of students' gains and progression.

In a practical point of view, it is unlikely that most instructors who use this system would have a strong IT background, it has been designed to take into consideration the ease of future promotion. It is therefore organized in such a way as to enable instructors to independently manage the entire curriculum. It seeks, as much as possible, to take account of whatever situations may arise, providing a range of functions that instructors would find useful. To that end, this system is wrapped up in a simple graphic and user-friendly interface, making the system management much easier for instructors.

Findings

Quantitative results in this study are divided into two portions. The first portion considers the learning curves of six assignments of self-, peer- and instructor-assessment in a whole semester. The second portion is to observe the students' preferred learning tasks in this study.

The learning curves of six assignments of self-, peer- and instructor-assessment in a whole semester

In the first, author reported the learning curves of self-, peer- and instructor-assessment in these six works (Fig. 1). Author found the peer-assessment is closer to instructor-assessment than self-assessment. This result agreed with previous researchers' finding (Lennon 1995). Addressing cultural comparisons among Chinese and Latino Americans, Carson and Nelson (1996) found that in peer assessment, Chinese-speaking students' preference for group harmony prevented their critiquing peers' work. In this study, authors also found that students also tend to give their peers and themselves a great high score.

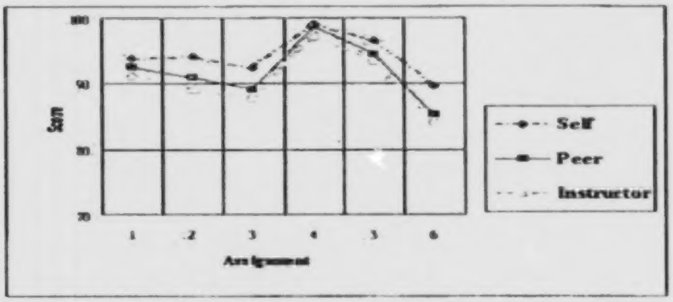

Figure 1: Learning curves (Mean score) of each assessment

The students' preferred learning tasks in this study

Author distinguished the work into open-ended writing assignment and programming project and asked the students to pick up one of the most favorite and fruitful wok. The result indicated that most students do favorite and learn more from the programming task (61, Chi-square=95.08***, df=4) than other five writing assignments (16, 9, 9, 12, and 2). Maybe this result just showed the natural character of computer science students.

Limitations

This study has been applied to undergraduate students undertaking an operating systems course at a research-oriented university in northern Taiwan. Students are almost consisted of seniors, juniors and some sophomores. Applying the same method to other subjects would not necessarily yield the same results, particularly for freshmen lacking the necessary academic skills and discipline.

Author has not mainly focused on the qualitative evidences of the progress of learners but there still are some quantitative results to show the learning curves of students and students' preference. Author would do a more deeper and qualitative researches in order to enrich the study of learning effects of this system in the near future.

Acknowledgments

The author would like to thank the National Science Council of the Republic of China for financially supporting this research under Contract Nos. NSC 90-2520-S-009-002 and NSC90-2520-S-009-003.

To Propose an Algorithm for Team Forming: Simulated Annealing K Team-Forming Algorithm for Heterogeneous Grouping

Eric Zhi-Feng Liu
Dept. of Information Management
Ming Hsin University of Science and Technology
Taiwan
totem@mis.mhit.edu.tw

Abstract: In recent studies, some researchers were eager for the answer of how to group a perfectly dream team. There are various grouping methods, e.g. random assignment, homogeneous grouping with personality or achievement and heterogeneous grouping with personality or achievement, were proposed. Some instructors could put some students in a team better via their experiences than some algorithms. And some algorithms would match students perfectly but in chance teams assigned by instructor also good enough. This phenomenon would stay continuance until a baseline algorithm is to be proposed as a baseline of comparison. Based on the above discussions, I have proposed a team-forming algorithm for heterogeneous grouping that could be used by other researchers to compare with.

Introduction

This algorithm was revised from K team-forming algorithm (Liu et al. 2002a), which similar to K Means clustering algorithm (Kaufman & Rousseeuw 1990), and simulated annealing K team-forming algorithm for homogeneous grouping (Liu et al. 2002b). In K Means clustering algorithm, it put closer data points into one of the K (1< K < total number of data points) clusters by distance measure. In K team-forming algorithm, also it put K similar students into a homogeneous team by distance measure used by K Means clustering algorithm. In simulated annealing K team-forming algorithm, author try to improve the answers gained from K team-forming via gradually searching the lowest variance or optimal answer. The simulated annealing process is a cooling process from high temperature (e.g. 100) to low temperature (e.g. 0). In higher temperature this algorithm would be with higher probability jumping from local optimal, and then in lower temperature this algorithm would gradually converge to a solution, which would be an optimal solution or a solution closer to optimal.

Author has revised the code of simulated annealing K team-forming algorithm for homogeneous grouping to simulated annealing K team-forming algorithm for heterogeneous grouping. There are two possible ways of revision. The first way is to keep minimum inter-group variance. If there are nine students (with the following status: 1, 2, 3, 4, 5, 6, 7, 8, 9) and classify three students as a team, then the solution of minimum inter-group variance should be (1, 4, 7) (variance=9), (2, 5, 8) (variance=9), and (3, 6, 9) (variance=9). The minimum inter-group variance is abs(var([1 4 7])-var([2 5 8])) + abs(var([2 5 8)-var([3 6 9])) + abs(var([1 4 7])-var([3 6 9])) = 0, but the sum of variance of every group in the above is just 27. The second way is to keep maximum sum of variance of every group. If there are also nine students (with the following status: 1, 2, 3, 4, 5, 6, 7, 8, 9) and classify three students as a team, then the solution of maximum sum of variance of every group would be (1, 4, 9), (2, 5, 8), and (3, 6, 7). The sum of variance of every group in the above is 29.6667, which is great than 27.

Under my consideration, the purpose of team forming is to achieve the maximum performance of all teams in general. So my decision is to apply the concept of maximum sum of variance of every group in the code of simulated annealing K team-forming algorithm for heterogeneous grouping.

Findings

Author has applied this algorithm to cluster 3 (let u=3) students into a team of 9 (let i=9) students (3 teams) and 90 (let i=90) students (30 teams) with characteristics from 1 to n (n=9 and n=90). The Figure 1 showed this algorithm would find pretty well team forming in maximum sum of variance of every group but worse team forming in minimum inter-group variance when n equal to 9. Figure 2 showed this algorithm would also find pretty well team forming in maximum sum of variance of every group when n equal to 90. This algorithm would be used as a team-forming algorithm for heterogeneous grouping and could be reproduced in future experiments.

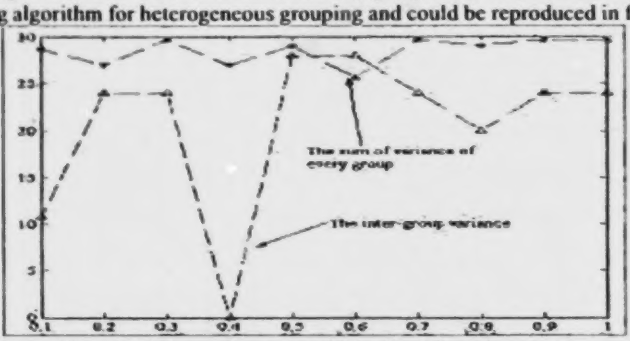

Figure 1: The performance of this algorithm when n = 9

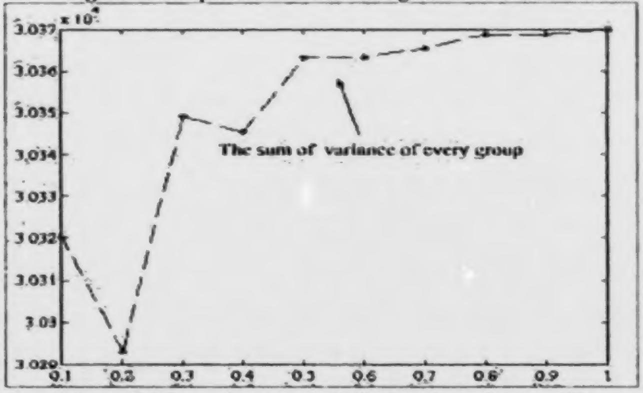

Figure 2: The performance of this algorithm when n = 90

Designing Digital Data-Gathering Techniques in a Busy Hospital Environment

Chris Livermore, O.P.E.N. The University of Melbourne, Australia. chrisliv@unimelb.edu.au
Tim Lambert, O.P.E.N. The University of Melbourne, Australia. lambertt@unimelb.edu.au

Abstract: Numerous communication devices flourish on the market but more often fail to meet set objectives due to unforeseen technical issues. More often the mixing and matching of technologies can circumvent these issues whilst appearing to the user as an easy to follow instrument. This article describes a method for more reliable data collection, and the resources necessary to overcome the technical problems in a busy mental health environment. We highlight the authoring and interaction between a personal digital assistant (PDA), a CD-ROM, and an online database to meet set goals.

Introduction

The range of information delivery technologies in the market today creates difficultly when designing an efficient mechanism for data gathering and the provision of associated educational resources. Off-the-shelf technology products rarely cater for all the eventual developmental needs in an evolving project and can be quite costly. This article describes how a Personal Digital Assistant (PDA), a CD-ROM program, and an online database can operate in a streamlined fashion to aid research activities within mental health programs. We highlight the devices, programs and communication pathways developed for use in a mental health research study (Lambert et al. 2002).

The requirements of this study were to:
Identify barriers to the identification of co-morbidity in patients suffering from persistent psychotic illness and; Gather and transfer this information efficiently to the researchers.

The former was addressed by the inclusion of an educational CD-ROM resource rich in digital video training aides (out-of-office training days were not available). Clinicians vary in expertise and experience hence this resource enhanced clinical recognition skills and thus more accurately identified instances of co-morbidity. The latter is plagued by such differing information sources such as questionnaires, cognitive assessments, physical examinations and laboratory screening tests. The paper-based system has proved to be cumbersome due to large patient numbers, multiple clinic locations, and lost or incorrectly submitted data (Chesanow 2000). In addition, a transcription error-prone duplication of data entry must occur to re-input the data into the digital domain. To circumvent this problem the clinician would use a Personal Digital Assistant (PDA) with an authored program to easily convert clinical information into stored data with later transfer to an online database. The PDA, in this case running the PALM ™ OS, is fast becoming a valuable tool for a multitude of medical uses (Duncan et al. 2000, Klainberg et al. 2002) and in addition proving appealing to health professionals (Noble 2000, Rothschild et al. 2002, Washburn 2001). Research also confirms the clinical benefits of PDA programs, CD-ROM education, and online information delivery (Fraser et al. 1997). However, there is a paucity of research proving the combined communicative benefits of these three media elements acting as a single 'flow-through' evaluation mechanism.

Aims

We aim to show that successful development is possible for the budget-tight, mid-sized unit, where development criteria such as cost-effectiveness, ease of use, and program flexibility, are essential. Discussion will include authoring tools used that call for a dedicated hand with multimedia skills without the requirement for a team of individual information technology professionals and programmers.

Usability and a streamlined, intuitive interface across all three media was a critical factor in the implementation of this program.

Goals:

To develop an efficient adaptable hand-held method of data collection for a combination of standardized medical and psychiatric questionnaires, cognitive assessment, physical examination and laboratory screening test information.

To provide computerised education and training (mainly video based) to mental health clinicians and primary care physicians which maximizes the detection and treatment of co-morbidity in patients suffering from persistent psychotic illness.

To create a user-friendly method for online data delivery, data storage, as well as a contact point for program updates/research information.

Discussion

The limitations set on this article has meant the exclusion of a detailed methods section. Collecting clinical information itself is an intensive process and inefficient when the data is incorrect, unreliable or simply missing. The mechanisms mentioned in the full poster/article, combat these difficulties providing the researcher/clinician with on-the-spot evaluation help as well as educational resources if needed. Whilst the technologies discussed are proving successful, it is hoped that they may be used in settings to enhance the accuracy and collection speed of a broad cross-section of data. Eventually, for this study, it may enable the development of screening algorithms for routine clinical use in populations within public mental health facilities.

Students Perception on Skills Needed for Successful On-Line Collaborative Projects

Dina Loebl, Ziva Levy, Tel Aviv University, Israel

This study focuses on the skills needed to be an effective learner, in an online collaborative learning environment. Sixty-five graduate students in the school of Health Professions at Tel Aviv University, Israel, participated in this study. All the students took classes that required on-line collaborative projects. In a questioner, students were asked to identify skills and attributes, that they believe, are needed to become an effective participant in an on-line collaborative project. The data was analyzed and a profile of such a team member was compiled.

Protecting The Natural Voice
The Dublin University Voice Care Program

Theresa Logan-Phelan, Center for Learning Technology, Trinity College Dublin, Ireland, tlgnphln@tcd.ie

Pauline Sloane, Clinical Speech & Language Studies, Trinity College Dublin, Ireland, psloane@tcd.ie

Abstract. An audit of all voice-related problems among trainee teachers in the University in Dublin showed an incidence of 52%, indicating that the present curriculum is ineffective in addressing preventative voice care among teachers. Searches further a field showed that no such complete voice-care program exists on the Internet. Here we present a preliminary on-line program of voice care for teachers based on constructivist theory, which has been tested in small samples of trainee teachers reporting voice problems and on control groups including teachers with no voice problems, non teachers, and Speech and Language pathologists.

Introduction

This project arose in the context of teacher education. It was found (Miller and Sloane, 2002) that 52% of those students registered for the higher diploma in education at the University of Dublin, Trinity College, presented with a vocal difficulty at some stage during their periods of teaching practice. The care of the professional voice was taught to postgraduates registered for the higher diploma in education using a traditional discipline based approach with little emphasis on Web-based instruction. Internal review mechanisms and student feedback, plus the high incidence of voice problems mentioned above, highlighted the deficiencies in the traditional course. In view of the need for a widely accessible program for voice care addressed to the teaching profession, and of the absence of such an instrument so far on the Web, The Dublin University Voice Care Programme was developed making such a program available (Logan-Phelan & Sloane, 2002). This paper reports on how the preventive Web-based program for the voice care of the teacher works to provide users with technical knowledge of the *psychophysiology* of the voice to empower personal change.

Methods

The course is designed using the constructivist theory, allowing teachers (the user) using the program to engage in active, intentional and cooperative learning on the care of the professional voice. Learning tools include -

- Self-assessment tools. Students must assess their voice, and decide if they are experiencing vocal problems. *Constructing the solution requires learners continuously articulate what they know about the problem and reflect on its sufficiency for solving the problem* (Jonassen & Peck 1999).
- Audio clips to demonstrate various vocal exercises. *Hearing and seeing tasks embedded in a real-world context makes the tasks more understandable* (Jonassen & Peck 1999).
- Self-assessment exercises and quizzes are employed to facilitate the users, so they may test their learning on the content. *Students involved in solving complex problems are active learners.* (Jonassen & Peck 1999).
- A discussion board is employed so the users participate in social learning and collaboration. The discussion board may also be used as a support group for those with voice problems. *Learning most naturally occurs, not in isolation, but by teams of people working together to solve problems* (Jonassen 1997).
- Original FLASH animated graphics to explain the bio-mechanics of voice production.

The environment is intended to help users in three areas - -

- Develop self-awareness in recognition of voice problems at an early and preventive stage.
- Feel empowered to make changes in their attitude to voice care.
- Decide on their own solutions and make personal decisions on action they should take to preserve and improve voice care.

Results & Discussion

The Web-based course may be seen at: http://www.webvoice.tcd.ie and results have been obtained by way of written feedback from 20 users belonging to four categories; 1) Teachers reporting work-related voice problems (target group), 2) Teachers not reporting voice problems, 3) Other voice professionals not involved in teaching and 4) Professional Speech and Language Therapists.

All users reported learning something new from the programme, but those professional voice users felt the programme not only offered real learning in the form of content but it also motivated and empowered them to make personal change in the care of the professional voice.

The teachers experiencing voice problems felt the programme was a tool on which they could look for support and guidance on how to deal with their voice problems. The programme had the most impact on those users who were most in need, i.e. teachers with voice problems. The programme offered users who were more vulnerable or more in need, confidence to make personal changes in how they use their voices. With the caveat of the small numbers, consisting of people with different learning styles, we are satisfied that the programme offered users an environment which could give them the amount of depth they required to meet their personal requirements on voice care.

The non-professional voice users shown a polite interest in the programme, they were surprised that voice care was so in-depth. While both groups of teachers were very impressed with how the programme enhanced their self-awareness on voice care, teachers not experiencing vocal problems, stated they would work on using the programme as a preventive instrument.

The results show that the care of the voice for teachers is indeed a topical subject. There are a large number of teachers and other voice professionals aware that they are experiencing voice problems, but they are not aware that such disorders can be prevented if they take proper preventive measures. Professional voice users should take a holistic approach to voice care, coordination of breathing, posture, relaxation, voice are required to ensure a voice in harmony with the emotions and the communication. Most people are not aware of what voice care entails, while they realize voice care entails some voice exercises, they do not realize that breathing, posture and relaxation play a major role in ensuring a healthy voice.

Title: Depressed? Go online! (or: how to get counseling via the internet)

1. Introduction

In the fast-changing world of the internet, an exciting new feature towards helping people with psychological and general counseling problems are being developed. There are several advantages to such a kind of help for counselees and all the possibilities of the internet should be fully explored, even advantages that have not been researched or thought about. As the way of "doing counseling" develops, new avenues will be opened and may be new problems encountered. However, this should not inhibit the researcher and internet-user to fully utilise this possibility.

The paper will be divided in three parts: how the first stage of this development is handled, what the advantages and/or shortcomings are of such a system and finally: what new possibilities may arise and what future development may happen.

2. How this evaluation works

Any person experiencing a psychological/life problem, can get access free of charge to an interactive questionnaire of 25 questions about "quality of life" on a website developed especially for such a purpose, e.g. www.drhansdreyer.co.za . After answering the questionnaire online, the preliminary "diagnosis" is shown and the user go to a next level where a comprehensive analysis is given of the suspected problem; eg. phobia, depression, post-traumatic stress etc. A short definition is given as well as a medical, psychological and theological description of the problem. At this point a list of participating counselors, like psychologists, pastoral counselors, social workers and psychiatrists and where they can be reached, is communicated to the user, who can register online by paying a fee and get access to one of the professionals mentioned above. When the person gets in touch with the therapist, the data is already available and it can give the therapist a quick preview of what might appear to be the problem of the counselee. Counseling can now start either by way of e-mail, phone, videophone, chat rooms or via the internet itself.

3. Advantages/disadvantages

There are many advantages in doing counseling via the internet. For the purposes of this paper, this focus will mainly fall on e-mail communication. Although some of the advantages may also be applicable to other forms of internet counseling. The advantages and disadvantages are shortly mentioned. Note that they are not extensive and are not necessarily in opposition to each other.

Advantages	Disadvantages
• Immediacy	• No interpersonal interaction (body language etc)
• Anonymity	• "Disqualification" (stop writing, delay answering)
• Accessibility	• Less time as issues and demands grow
• Speed	• Hide behind the internet
• Cure against loneliness	• No "personal actions" like card, visit
• Not limited to locality and time	• Easy to dodge negative issues
• Record of what has been written is kept	• Can become addictive (daily routine)
• Reference easily made to other internet help	• Ethical issues (child molesting should be reported)
• Time for reflection/thought before answering	• Payment of therapist
• Attractive to individualistic approach	• Control over therapist?
• Data available which might not be personal available	• Therapist cannot evaluate reaction on counseling
• Time-saving, evaluations already done	• Possibility of extra-marital and other unhealthy relationships

4. New possibilities

As mentioned in the introduction, there are many exciting new developments in the field of counseling w via the internet that might be pursued, some of which might not even be contemplated.

4.1 The chat room

Counselees with different kinds of problems, like *inter alia* phobias, addictions etc. may use chat rooms to communicate their frustrations, progress in therapy or even share helpful hints regarding their common problem. All the advantages mentioned in 3 above will also be applicable here. Organizations like AA (Alcoholics anonymous) and GA (Gamblers anonymous) have had great success in providing a *support group* for the person with a problem. The chat room can provide for such a need, without the element of "personal shame" or shyness.

4.2 Direct communication between the counselor and counselee via computer links

This might be helpful for a one-on-one contact where with a camera the one can see the other (sometimes the counselee prefer to see the counselor but not be seen him/herself). This gives the opportunity to *hear* from someone's voice certain halo data which are absent in e-mailing. Since the counselor may be abroad and never see the counselee again, brings an openness which might not happen in the usual counseling where there may be other contact in society as such. (In the South Afican situation where many young people work abroad and sometimes have great stress, this is a very usefull way of counseling, especially in one's own langauge!) This is of course a more personal approach that e-mail only. Tapes of the camera may be kept for later reference for either the counselor or counselee.

4.3 Video phones

The researcher suggests that video phones of all could be used as a viable option which may be similar to 4.2 although a computer may not be necessary. Again, seeing each other may be more personal, but not as exposing than ordinary counseling in a counselor's office.

4.4 Other applications

Although the researcher is not aware of any other ways of evaluating and doing counseling via the internet, other possibilities may be developed, like switching into support groups world wide, listening to them and participating in their discussions, going into databases of people with similar problems and be able to communicate with them in the various ways described above. Technology may develop to the point where blood pressure or heart beat might be taken via the internet or other medical procedures and tests which are unthinkable at this point.

5. Conclusion

This paper suggests that there are already very practical and user-friendly ways in which psychological evaluation and counseling can be done via the internet and different applications thereof. The advantages and disadvantages of this method is discussed and finally new, exciting ways in which the internet can be used in the future with regards to counseling are also mentioned.

EduKBr Portal: an Environment Concerned with Quality of Information in the Brazilian World-Wide Web

Marisa Lucena
KBr Project, Padre Leonel Franca Foundation
Pontifícia Universidade Católica do Rio de Janeiro
Brazil
mwlucena@kidlink.fplf.org.br

Valmir Soares Azevedo
KBr Project, Padre Leonel Franca Foundation
Pontifícia Universidade Católica do Rio de Janeiro
Brazil
valmir@kidlink.fplf.org.br

Abstract: This paper presents EduKBr Portal, an educational, thematic portal on the Brazilian World-Wide Web. EduKBr Portal is segmented in sites that present projects, activities and services based on users day-by-day lives, multicultural aspects, and different school subjects. This educational portal is structured in order to achieve quality educational activities and content, to facilitate the access to and use of technology, to provide a democratic access to documents and contents, and maintain a motivating, attractive, ludic and safe place on the Brazilian Web.

Introduction

It is notorious that the Internet offers mechanisms that facilitate communication, cooperation and access to information. It has, therefore, become an indispensable tool for a conscient education, which takes into consideration social changes and the acquisition of new knowledge through collaborative instruction. Considering that cooperative learning depends on the motivation and on interactions obtained, there are many websites on the Brazilian Web that aim at this objective, for example, Kidlink in Brazil (http://venus.rdc.puc-rio.br/kids/kidlink), Doce de Letra (http://docedeletra.com.br), among others under the category "Education" or "Infantile Education".

However, we have noticed that, in general, there is difficulty in interaction regarding an effective and regular participation by adults and youngsters, and, also, regarding the quality of the contributions made by them (Lucena 1997). We believe that some users (specially teachers) either (a) have not developed the skills and the mentality necessary for the efficient use of Internet resources, (b) still are in an initial-to-intermediate level in relation to the use of Internet resources (e.g. exchange of information by e-mail), (c) do not have access to adequate equipment, or (d) still need to participate in activities and projects that are designed in a traditional way in order to become more confident and be part of the Dynamic Learning Community on the World-Wide Web (Win, 1993).

Therefore, participation and navigation on the Internet may foment incidental learning, which is very profitable. But, as field studies have showed (Wilson 1996), it is necessary to offer a structured environment in which the learning process is not submited to random happenings, and offer an environment that facilitates participation of schools and the majority of Brazilian users, who still are in an initial and exploratory phase in relation to the use of resources offered by the Technological Education area.

The EduKBr Portal Environment

The EduKBr Educational Portal (http://www.edukbr.com.br) is a specialized, thematic portal which is maintened and implemented by the interdisciplinary and organizational partinership between the KBr Project team and EduWeb, a company specialized in development of material and environments for distant-learning/formation.

Whereas KBr Project participates in this partnership with its team of experienced consultants and specialists from Pedagogy, Psychology, Logopedia, Biblioteconomy and Arts to specify, develop and maintain the contents of the environment, EduWeb contributes with its professionals specialized in WebSolution/Design, Economy, Administration, Law, and Marketing. These professionals are responsible for the general administration, law-related issues, and the publicity of the portal. In this case, the main objective is to search for resources in order to assure the autonomy and continuity of the project. This partnership between KBr Project and EduWeb is also supported by professionals from LES (Sofware Engineering Laboratory) from Pontifícia Universidade Católica do Rio de Janeiro (PUC-Rio).

The thematic spaces/sites of EduKBr Portal relate: (a) teaching and learning process, (b) distant courses planning, (c) Human Resources fomation, and (d) establishment of a Learning Dynamic Community on the WWW *with* (a) day-by-day lives of adults and youngsters (e.g. entertainment, culture, etc.), (b) some multicultural aspects, such as Information Society, globalization, Distant-Learning/Teaching, and (c) subjects suggested in MultiEducação Curricular Guide (Lucena & Soldon 1998).

At first, the development team from EduKBr Portal chose, implemented and launched those which are the first thematic environments. Nevertheless, there was the necessity to open the portal to the submission of new sites and new innovative ideas from the community. In order to be integrated to the portal, these sites and/or ideas must go through a qualitative evaluation of content and interface performed by and editorial board constituted by professionals from Education, Psychology, and Web Design. The Law Team is responsible for copyright issues and for the inter-relation between proponents and participants of the portal. The principal commitment of EduKBr Educational Portal is with quality of information and quality of the services offered in its environments.

EduKBr Portal uses an integration tool that is a relational and referencial search engine, called Estúdio System (Salvador 1988). This tool simplifies navigation through the thematic spaces within the portal, which, in spite of having autonomy in content, visual identity, technological development, information, activities and services, allow: (a) an effective inter-relation between and query to the resources and data distributed in each of the sites of the environment, and (b) navigation and democratic access to the Internet. In this case, for example, users can retrieve and use a piece of information or application that is located in a determined thematic space without the necessity of leaving the place where they are or leaving the portal itself. Therefore, this mechanism guarantees security and interactivity issues inside the portal.

BEST COPY AVAILABLE

The Thematic Websites of the Portal

EstúdioWeb
A cooperative environment idealized and maintained by the KBr Project Team. The website offers both a search engine that supports web-based educational practices and great virtual repository of websites selected and analysed qualitatively.

Celeiro de Projetos
Celeiro de Projetos' objective is to develop the Portuguese language and be a point of reference regarding the use of the Internet. It presents cooperative projects based on the indication of a website that is previously selected by the team.

Arte Manhas
This site aims at the appreciation and production of various artistic languages through processes of experience, reflection and comparison. The activities proposed start from a personal cultural and historic context to reach a greater sensibility regarding interaction and multiplicity of manifestations existent in the world of arts.

Leitura&Escrita
Leitura&Escrita dynamizes reading and wrinting and uses technological tools, specially web resources, for this purpose. It is more than a repository of links or a digitalized version of a library; it intends to transform authors, readers, writers and illustrators into a dynamic community that privileges the joyful and creative contact with texts, images and the infinite literary universe.

Mochila nas Costas
This site's themes are the study of geography and ecology focusing on the notion of natural space and dynamic relations established so that individuals become constructor and preserver agents of the habitat and of the quality of life on Earth.

Profs Online
This service aims at helping students develop procedures necessary for the clarification of their doubts. Profs Online does not offer answers, but leads students to think about how they could solve problems.

Colunas do Portal
In partnership with PUC-Rio's Central Coordination of Distant Education, Colunas do Portal offers recent and original articles on various themes from education professionals formation and the process of teaching and learning to Dynamic Learning Communities interaction.

Oficina de Aprendizagem
This site is a virtual classroom specially designed for teachers and students. In this classroom, considered a learning workshop, online courses and workshops complement the curricular grid of the Elementary and High curricula. Oficina de Aprendizagem aims at motivating teachers to create their own online courses using AulaNet.

Expected Results

Great is the number of portals in the web. They are characterized by the power of collecting pieces of information of various types and cataloguing them to make possible for users to find them easily. However, many of these portals treat education as one of their virtual stores, i.e, they are horizontal portals.

EduKBr Educational Portal's pioneerism is due to: a) the verticality of its design, b) its commitment with Information Technologies applied to the formation of Dynamic Learning Communities on the web, and c) the use of resources in Educational Technology for a quality Distant Education.

EduKBr Portal intends to present and apply activities and solutions for problems in our socio-cultural-economic reality and in our educational system. These problems were cited in an ethnographic research developed in a doctorate thesis (Lucena 1997), and they can be exemplified as folloing: a) cultural diversity, b) socio-economic unequality, c) difficulties of communication in foreing languages, d) late schools computarization, e) necessity of pedagogical support in specific content, and e) motivation for participation.

In the long term, EduKBr Portal should achieve and/or maintain the following essential goals: a) to offer Brazilian schools a space of educational possibilities and activities, b) to simplify the use of technological resources in order to facilitate access, interaction, and tools integration (e.g. search systems, video conference, etc.), c) to provide a democractic means of access to documents, d) to maintain a motivating, attractive, ludic, and safe place, and e) to combine curricular and extra-curricular items compatible with the socio-cultural profile of the country.

Applying qualitative research in e-learning. Discussion and findings from three case studies. Setting the base for a knowledge management oriented metadata schema.

Mr. Miltiadis D. Lytras
Athens University of Economics and Business,
Greece
Email: mdl@aueb.gr

Abstract

The case of learning in digital economy 's era is a fascinating phenomenon. The complexity of learning integrated with the diversification of new technologies set a dynamic landscape where the performance seems to be the overall objective of combined efforts. Our approach tries to investigate the phenomenon from a "myopic" point of view. The starting point of our research effort is the acceptance for the existence of a direct relation that brings togethe learning, new technologies, pedagogy and knowledge management. In this paper we present the initial findings from the application of qualitative research methodology. More specifically we discuss three case studies (multiple case strategy) concerning e learning systems implementation and we discuss the way that knowledge management theory can support in practical ways the performance of e-learning systems.

1. Introduction

A common practice in academic institutions or business units is the employment of new learning technologies in order to support the human resources management. In most of cases the adoption of several Learning Management Systems, provides a context for exploitation but unfortunately the achieved learning performance is rather inadequate (Lytras and Pouloudi 2001) (Lytras and Pouloudi 2001), (Lytras, Pouloudi et al. 2002). The enormous efforts that have to be paid in order to develop e-courses have risen a critical questioning on whether the invested money and the employed human capital are utilized.

After the critical reviewing of e-learning literature and the analysis of several cases presented on conferences and described in journal articles, we decide to put the emphasis of our research on parameters that could provide empowerment in e-learning. Additionally the participation of our research team called ELTRUN (http://www.eltrun.aueb.gr) in Athens University of Economics and Business in projects concerning Knowledge Management gave as a hint that these two areas could be integrated. Several conflicting opinions about the convergence of knowledge management and e-learning realized a dialectic context of reasoning and justification (Allee 2000), (Hodgins 2000), (Hong and Kuo 1999), (John Garrick 2000), (K.-D. Altho, F. Bomarius et al. 2000).

The fact that knowledge management concentrates on knowledge processes and knowledge artifacts (Mentzas, Apostolou et al. 2001) promoted the initial step in our approach. The underlying logic is extremely clear. If in an e-learning environment we can justify several knowledge processes that construct a kind of knowledge artifact that is finally diffused to learners then the information technology can analyze the technical standards and the required applications for the support of our conceptualization.

This challenging situation sets a context that promotes the research in reusability of knowledge resources. A realization of reusability can be based on semantics that enrich general knowledge resources (e.g. an article, a journal paper, a PowerPoint presentation, etc.). The ultimate objective is to expand the customisation capabilities of learning environments and knowledge management seem to be a well justified mean for the achievement of such a goal (Lytras and Pouloudi 2001), (Lytras, Pouloudi et al. 2002).

2. Conclusions

In the next section in which we will provide a very brief tabular presentation of the convergence of theoretical findings and empirical result that jointly provide some conclusions.

Key themes	Theoretical findings	Empirical results	Conclusions
E-LEARNING CONTENT DEVELOPMENT AS A CONSTRUCTIVE KNOWLEDGE MANAGEMENT PROCESS	(Mentzas, Apostolou et al. 2001) claim that knowledge processes is a value carrier. This theoretical abstraction utilized the propositions of other researchers (Hahn and Subramani 2000), (Nissen, Kamel et al. 2000) who provided several life cycle descriptive models for KM	All 3 cases provided information that justifies e-learning as a KM process. Specific phases usually informal provide a context for the diffusion of learning content to users. Several problems unfortunately and limited management mechanisms decrease the performance	The conclusion is that the knowledge process concerning e-learning realization range to a wide spectrum that incorporates two general pillars: General knowledge management processes and process for the adoption of knowledge to learning objects.
LEARNING OBJECT AS A KNOWLEDGE ARTIFACT	(Mentzas, Apostolou et al. 2001) claim that knowledge artifact is a way for realizing the knowledge management. Several researchers (Nonaka and Takeuchi 1995), (Heldund and Nonaka 1993), (Boisot 1987)	In all cases it was recognized that learning content was not knowledge in its true sense since there was an absence of metadata or semantics that would enrich the semantic density of learning material. But it was also stated that	The development of learning content requires the attachment of metadata in order to become a qualitative transformation of information to knowledge. This requires excess effort from educators. The overview of several metadata schemas (LOM,

	where a questioning concerning what is knowledge is provided. The justification of learning object as a knowledge artifact drive an excessive analysis	codification and diffusion is of critical importance for the learning objects. Additionally a number of other value ingredients of the learning product were described from interviewees. Their realization in e-learning settings requires more sophisticated techniques	GEM, Ariadne, IEEE LOM, IMS, DC) seem to bee inadequate to support the learning dimension of e-learning
METADATA JUSTIFICATION ANDE-LEARNING PEDAGOGY SUPPORT	(Shuell, 1992) & (Bloom and Krathwohl 1984) provide a context for providing different learning value. Learning processes or learning objectives are the value drivers.	Unfortunately the learning performance of three cases was based on static learning scenarios. It was evident that this dimension of e-learning implementations was to weak and needed support.	The detailed analysis of learning processes can cause a significant contribution specifying metadata elements for specific learning processes. This secures and the dynamic nature of e-learning since its learners could get a different value selecting different learning processes.

This approach is not ending here. A systematic modeling of metadata for learning processes has already finished. A prototype of a tool called **Semantics for Learning™** is already developed. This interoperates with a prototype of the **Dynamic Elearning Case Builder™**. We believe that very soon we will be able to launch a new platform based on the abstractions that mainly enrich information resources in order to build re-usable learning content. Our research unit (www.eltrun.aueb.gr) welcomes any comment or contribution concerning the key ideas presented in this article.

E-Learn is about business:
A business model for the digital economy.

Miltiadis D. Lytras

Greece
Email:mdl@aueb.gr

Abstract

From time to time, the e-commerce landscape is enriched with several business models that promote new value propositions to a number of stakeholders. The attractiveness of e-, in any business, rises a questioning concerning the viability of the justified business model. The phenomenon of the digital economy in our paper is investigated from a knowledge-based perspective. The digital economy is the economy that exploits knowledge and our business model facilitates the exploitation of knowledge in business and academic environment: E-learn business model is a combination of strategy and conceptual abstraction with a clear market orientation.

1. Introduction

Considering the phenomenon of digital economy numerous approaches try to explain the self-evident: That digital economy is more demanding in requirements, is more competitive and its value proposition can be evaluated more rigidly from the various target groups. According to (Allee 1999) "this new economic era has been referred to by various authors as: the Intangibles Economy, the Knowledge Economy, the Experience Economy, and the Idea Economy. Whatever name it goes by, it is rewriting the rules of business and forcing a radical rethinking of corporate value and business models". (Lytras and Pouloudi 2001) after a critical reviewing of several implementations of e-learning systems concluded that e-learning is providing limited value especially in the cases of simple adoption of e-learning platforms. Successful implementation of e-learning requires the same management commitment as other mission-critical organization-wide initiatives. Most of all e-learning needs to be compelling to the audience it targets, offering the learner a resource that is seen as appealing, valuable and productive to their goals and aspirations".2. E-learning marketplace characteristics. (Ruttenberg, Spickler et al. 2000) uses three key variables in order to provide a description of the e-learning market. These variables are:

- **Markets Served:** Academic, corporate & consumer, **Revenue model:** Contracts, pay per use and ads/sponsors, **Core Offerings:** Contents, services & technology, **Types of Content:** ?? , business skills, life style, academic, custom, **Types of Services:** Content distribution, consulting, implementation, eCommerce and community portals, **Types of Technology:** Learning Management Tool, content creation tool, delivery platform, collaboration tool.

One of the major observed problems in e-learning is the absence of standards capable to justify e-learning as a value-adding proposition. After many years of research in our research unit ELTRUN (http://www.eltrun.aueb.gr) in Athens University of Economics and Business we tried to justify the convergence of e-learning and knowledge management using an approach derived from e-commerce.

2. Value proposition – The underpinnings of E- 4. E-learn business specification

The E-learn business model is not a simple abstraction or a common organization of thought. The complexity of learning as a cognitive process, the technology imperatum, and the special features of Internet as a learning medium make the success of such a model a difficult goal. The desired unique proposition that this business model promotes requires an extensive analysis of several aspects. In the limited space of this article we are summarizing the main aspects of this model:

a. **Market Focus**: Academic Institutions & Business Executives Training
b. **Products:** A new metadata knowledge management oriented schema. A new Tool called Semantics for Learning ™, capable to catalogue information resources with the proposed semantics model (A set of metadata that focus on learning. This focus differentiates the proposed metadata schema from all the other standards such as IMS, DC, SCORM, LOM). An integrated E-learning platform called Multidimensional Dynamic Learning Case Builder ™ that packages the learning content using learning processes and not learning modules. Each learning scenario is a combination of learning processes.

c. **Innovation – Unique Proposition:**
The organization of knowledge in distinct objects, small structural components, is the basis of reuse. In the case of customized learning the same learning content can be used in many ways due to its integration with other knowledge objects. Our approach is based on two clear assumptions that initiate the whole research: A learning object is a synthesis of knowledge and metadata that expand further the learning effect of knowledge. From this perspective an e-learning environment has to utilize a learning objects base. A critical question is which metadata can we use in order to increase the

learning effectiveness. A learning process is an abstraction of a logical sequence of learning activities or tasks. The conceptualization of learning processes determines an interface in which the components of a learning object can be realized. This layout is a value container, which is utilized by the embodiment of learning object. The critical question is which learning processes can we use? And is there any hierarchy of learning processes that determine different value layers. The underlying issue behind the packaging of knowledge is the reveal of a key idea that will support the accomplishment of a metadata scheme. Our proposition that has been developed after many implementations of e-learning projects in our research unit, ELTRUN. (www.eltrun.aueb.gr) is that the convergence of knowledge management and e-learning is realized through an integrated life cycle model. Each step in this model that represents a value adding process. Each step sets a context for questioning about the required metadata that have to be attached to a generic knowledge source in order to formulate learning object. The first cycle summarizes a general Knowledge management framework where 6 processes / activities (Relate / Value, Acquire, Organize, Enable Reuse, Transfer, Use) make possible the management of knowledge object. The second cycle stands due to the assumptions that learning requires a further adoption of general knowledge sources. The six processes of the second cycle in figure two justify a learning orienting enrichment. The engagement of learners with the e-learning environment is becoming true through the employment of a number of learning processes.

d. **Strategy:** Differentiation. The proposed products of the model are differentiated from all the available in the relevant markets. Metadata industry is rather inadequate to support dynamic learning since it is focus on cataloguing purposes. LMS platforms are not really learning oriented in the sense of realized pedagogy.

e. **Technology Focus:** XML but based on concrete conceptualizations concerning e-learning scenarios, learning processes modeling and knowledge management.

f. **Pricing policy:** Mixed. Extensive promotion in the first two years.

3. Conclusions

The overall approach described in the limited space of this paper provides a context for exploitation focusing on learning. E-learning is a huge market with billions of dollars spent its year. The refinement of this model and the development of products that where describe will penetrate the market just because the e-learning market is not as mature as it would be assumed according to the overall size in terms of learners and invested money. Knowledge economy forces everybody to construct value through learning. So the value is not an abstraction. Is the cumulative and incremental ability of everybody mind to exploit the knowledge wealth and to prepare its cognition for new ideas and constructive thinking. E-learn intends to be the business model that proves that information technology is good not only for selling products on the net but mainly to support sophisticated mechanisms that support knowledge workers to manage effectively their most valuable asset: The knowledge. Is it imagination more important than knowledge? Yes, but only in the cases that creates knowledge.

Developing community in on online or web-enhanced course

It is our belief that for an online or web-enhanced course to truly be of benefit to students, a community has to be developed and the students have to believe they are part of the community and are taking an active role in that community.

To this end a unique online interface was designed that could be implemented for any Course or community. Every time a participant accesses the website they are given the realization that they are part of a group. The participant is given ownership over information on the system and is given the oppurtunity to contribute to the course/community.

The system includes a complete online grading program, database baqckend and several collaboration tools. It emphasizes ease of use for both participant and facilitator and is participant-centric.

Parallel Computing Performance Monitoring Tool for a Cluster of Computers

Authors: M. Madani (Student Author) x1aut@unb.ca
J. Light jlight@unbsj.ca
R. E. Shaw reshaw@unbsj.ca
Applied Statistics & Computer Science
UNB Saint John, Canada

Abstract: Clustering has always offered significant price/performance advantages to many high-performance workloads. The efficient use of both CPU and memory within each node of a cluster of computers is of center importance to cluster computing. This paper investigates the design of a CPU usage monitoring system for a cluster of eight nodes. Real time simulation has been used to introduce the contribution of each node to solving a parallel program. The tool developed allows a cluster of Linux systems to be managed from a single point of control.

Introduction

A cluster is a type of parallel or distributed processing system, which consists of a collection of interconnected stand alone computers (nodes) working together as a single integrated computing resource.

A node can be a single or multiprocessor system (PC, workstation, or SMP) with memory, I/O facilities, and an operating system. A cluster generally refers to two or more nodes connected together. The nodes can exist in a single cabinet or be physically separated and connected via a LAN. An interconnect (LAN based) cluster of computers can appear as a single system to users and applications.

Communication software offers a means of fast and reliable data communication among cluster nodes. Clusters with a special network switch use communication protocols such as active messages for best communication among the nodes. They bypass the operating system and thus remove the critical communication overhead, providing direct user level access to the network interface. This approach maximizes the range of options that provides mechanisms for evaluating alternatives and thus reduces the cost of backtracking from wrong choices.

The four distinct stages are: partitions, communications, agglomerations and mappings. Partitioning is decomposing the task (computational activities and the data it operates on) into several smaller tasks. The communication aspect focuses on the flow of information and co-ordination among the tasks that are created during the partitioning stage. In the agglomerations, the tasks and communication structures defined in the first two stages are evaluated in terms of performance requirements and implementation costs. Finally, the mapping is concerned with assigning each task to a processor such that it maximizes utilization of system resources (such as CPU) while minimizing the communication costs. These decisions can be made statically or dynamically at run time. The tool developed here will be used in the agglomeration stage.

Objectives

Predicting how well hardware works while solving a parallel algorithm and how it performs on different types of workloads is not possible. The goal is to develop system-monitoring software, which represents the CPU and memory utilization and the degree of contribution of each node to different types of workloads in the system. The existence of such a system is crucial to resource optimization in a cluster of computers.

Methodology

A dynamic table is created on the master node of the cluster, which keeps track of CPU utilization and memory cycles available in all the nodes of the cluster. This data can be retrieved through a sophisticated shell program or with the help of sockets. The table can be accessed via a well-interfaced program, which visualizes this trend with the help of graphical user interface.

The existence of a text file consisting of desired data from the nodes was assumed in the simulation process. This text file can be created by real time values obtained from the nodes of the cluster in future work.

Figure 1.1 gives the simulation results of a master-slave cluster consisting of eight nodes, while solving a parallel program. Figure 1.2 represents the overall resource allocation in a cluster of computers as a unified computing resource.

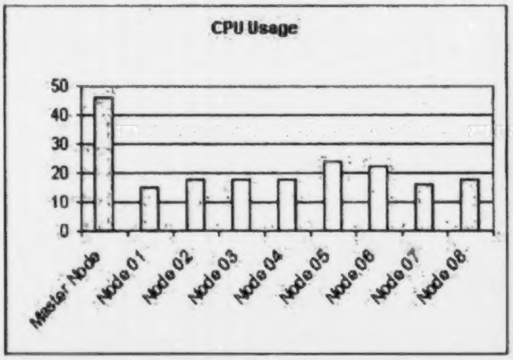

Figure 1.1

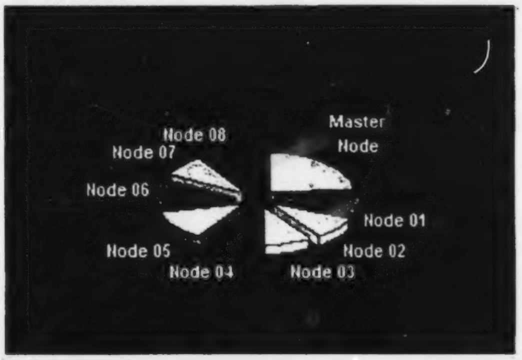

Figure 1.2

The performance monitor software is compatible with Windows based applications and can be easily updated in order to respond to future needs of the system.

Conclusions

We have established and evaluated the performance-monitoring tool, which represents the amount of workload and the degree of contribution of each node of the cluster of computers to solving a parallel algorithm. The performance evaluation of our approach leads us toward developing web management software to accompany the performance monitoring tool in order to achieve real time performance information in future work.

AN INTRODUCTION TO THE TEXT-TO-SPEECH XML-DRIVEN E-LECTURE DELIVERY SYSTEM

Wai Keong, Mak, Ngee Ann Polytechnic, makwk@singnet.com.sg

Abstract

One of this innovative implementation in education is Lecture on Demand (LoD) which integrates digitized and interactive video segment with purposeful learning activities so that students remained engaged during the session; students may access the LoD anytime, anywhere and any number of times they require. A XML-driven system, with in mind the issue of bandwidth constraints, and the surge in the use of e-Learning for education, is created to provide an easy-to-use web application that creates an e-Lecture with the use of MSAgents, and utilizing the Text-to-Speech engine to recite the salient information which would otherwise be text that the users read.

Introduction

The use of computers to provide an integrated environment for teaching a variety of disciplines has received much attention in recent years. Many frameworks have been developed for such purposes. The material provided by such courseware varies greatly from the provision of lecture notes and lecture support material to integrated and interactive tutorial packages. Until recently courseware has existed as standalone packages. However, with the advent of the World Wide Web (WWW) on the Internet and accompanying WWW (hypertext) browsers, such as Netscape and Internet Explorer, the provision of courseware has taken on a whole new dimension. In the last couple of years, we have created a global electronic library of unprecedented scope and value.

Researchers are posting new ways of looking at learning that promote:

- engaged, meaningful learning and collaboration involving challenging and real-life tasks; and
- technology as a tool for learning, communication, and collaboration.

As such, there is an increase in the use of the Internet as a platform for educational purpose. One of this innovative implementation is Lecture on Demand (LoD) which integrates digitized and interactive video segment with purposeful learning activities so that students remained engaged during the session; students may access the LoD anytime, anywhere and any number of times they require.

Many institutions are engaging streaming media as a mode of lecture delivery. Streaming media is real time delivery of audio and video over the Internet. The disadvantage of using such media is cited as unreliability of network, poor video quality and the lack of resources to connect to the service, and the lack of facilities such video streaming facility and large bandwidth for comfortable access.

An online system, with the following characteristics has been created:

a) use of XML files to drive the e-Learning: developers need only to modify the XML files to create the e-Lecture via a provided interface;
b) Use of text-to-speech engine to remove the bandwidth barrier (via MSAgent technology);

Feature of the System

Basically, the developer can create e-Lectures and updates the system, via an easy-to-use interface in the system. It includes:

- Title of the lecture

- Headings for individual section of the e-Lecture;
- The text to be read out for each section;
- Any stipulated action for the animated character (e.g. waving, winking, moving within the screen, etc.)
- A link to the slide / URL (if necessary)

Advantage of the system:

- Low bandwidth will still work: In essence, only text data are sent across the Internet to the recipients, as oppose to continuous streaming bits of video or audio packages which could choke the network and slowdown the whole system; users with a 56.6 kbps modem will still enjoy the lecture as those using broadband access;

- Use of XML to drive such system makes the integration with existing system plausible;

Implementation and Development

The author is moving the system into ASP.NET platform, which would allow seamless server-out of the e-Lecture to users using mobile computing devices like hand-held PCs, palm and even WAP devices.

In addition, surveys on its usage are being carried out on users of the system which will help to improve on the system.

In the implementation of such online learning lecture, it is proposed that:

- the learning segment has to be short (not more than 15 minutes)
- the segment has to peppered with purposeful synchronous /asynchronous learning activities:- This is manifested in the use of case studies that students must read and discussed before proceeding to the Analysis segment of the e-Lecture.

Conclusion

A trend is underway to more effectively blend e-Learning technologies with traditional learning approaches to create hybrid solutions. Doing so can create more powerful learning experiences by drawing on the strengths of the different mediums, while at the same time, helping people work through their apprehension with new technologies. Lecturers will be able to use this system as a supplement to their weekly routine lecture, to touch on rudimentary topics and areas, leaving more time for discussion and interaction during the face-to-face sessions.

As students have access to the materials via the computers, the instructors will be able to work individually with students as there is now less drudgery and repetition in their work and they would have access to more accurate appraisal and documentation of the student's progress (Kulik, Bangert & Williams, 1983).

This system is made, with in mind the issue of bandwidth constraints, and the surge in the use of e-Learning for education, to provide an easy, XML-driven web application to create an e-Lecture with the use of MSAgents.

The Assesment in "an on line Learning Model of Marketing" in a University.

Ma. Magdalena Maldonado Avalos
Instituto Tecnológico y de Estudios Superiores de Monterrey (ITESM)
Campus Estado de México
Mexico
mmaldona@campus.cem.itesm.mx

Abstract: At ITESM we are using the concept of "redesign", and this implies the use of a technological support called Lotus Notes-Learning Space. This concept implies a new role for students, the must have a more active role in learning. One of the advantages of Lotus Notes-Learning space is the "Assessment Center", it help the teacher for different activities: a) designing. applying and grading exams; b) To grade and return grades to the students in different activities like reports, task, etc.. and c) To audit the implementation of the course for different teachers in the same period.

The Assesment in "an on line Learning Model of Marketing".

At Instituto Tecnológico y de Estudios Superiores de Monterrey (ITESM), we are working in a new model called "Rediseño" (redesign). This means that we are working not only in the academic topics, we are considering also abilities, attitudes and worths. This model implies the use of a technological support called Lotus Notes - Learning Space. (LN-LS). One big change is the new role that a student has, he or she need to learn to learn, their role in more active than in the traditional educational models in the past.
In order to teach a class in this model required that all the design and the material that will be used during the period of classes be in the (LN-LS). Before to teach a class in this model a teacher must work in the design of the class. The LN-LS works using the following 5 database: 1) Schedule: Here we can find the programming of all kind of activities divided per week. (Our courses have 16 weeks); 2) MediaCenter: here we can find all the material that supports the course: Videos, abstracts, presentations, printed advertising, etc.; 3) CourseRoom: this is the space designed for make and send the homework (assignments) and the discussions, and also through this database the teacher can graded the tasks; 4) Profile: here we have all the information about the participants of a course (instructors and students). And also here the students can know their grades and the annotations that the teacher made related to their work.; 5) Assessment: This space permits to create different types of evaluation like : quiz, exams, survey, self-Asses. I will explain later about how we use the Assessment Center.
Each course is created in a server at each campus. Then each student needs to replicate the course in his or her Laptop through the use of the WEB or the Intranet. So all the activities that a course implies are in the (LN-LS). Actually I teach Basic marketing, and I designed the course in (LN-LS). In this model I scheduled all the activities, so the student can know in the beginning what he or she has to do during all the semester. The student can know what are the objective of the class, what the teacher expects the student has to do. Also he or she can know what is the homework (assignment), when is the deadline. Also the student can find examples of diverse products that are sell in Mexico. In each theme the student can find an Internet address of Mexican products, so he or she can visit it and he can learn a little bit more about how this companies use the Internet as a part of their marketing effort. This is a particular aspect of how Internet can improve the way of teaching Marketing. The students can see in a dynamic and actual way what is happening in the world. In the past, before the Internet and (LN-LS) we depend on what the companies want to publish in books, articles, magazines or journal.. Here are some examples:
http://www.profeco.gob.mx, http://www.ticketmaster.com.mx, http://www.jumex.com.mx
Another activity that is in the Marketing course is the use of the "Digital Library". Through the server the students at ITESM can access a lot of publications for example: Journal of Marketing, Journal of Marketing Research, Journal of European Marketing, etc. During the semester each student must read al least 3 articles of Marketing. The student makes an abstract and comments about what he or she read. Instead of going to a library they have access form any part. They only need a computer and connect to the ITESM through Intratec, and they can enter to the Digital Library. This is another benefit of the technology. Another important use of Internet and Intratec, is the possibility of put relevant information in the MediaCenter. We use a printed advertising of Mexican products or products that come form other countries but they need to be "tropicalized". The student can see the advertising and answer the different questions related to the topic of the week. They send the assignment through the CourseRoom.

THE ASSESMENT CENTER.

We use the Assessment Center for the following activities: First, a teacher can grade the activities that the student do in the CourseRoom, and we have the possibility to return the grade to the student by (LN-LS) with the comments *related to how the student did the task, or to suggest what the student need to study.* Second, here it is possible to create a bank of questions, in order to create exams. The program has the option to randomize the questions, so the exams are different for the students. There is four type of questions: true-false questions, multiple choice questions with a single answer, multiple choice questions with multiple choice, and the open questions. In the first 3 options it is possible that the program graded the questions. One of the objectives that we are working on is to increase the bank of questions with the participation of different teachers. We increase questions each semester. One advantage of using the exams in the Assessment Center is that it doesn't matter who is the teacher, the students have the same kind of exams, so there is a big possibility that the students learn the topics that were designed. Third, through the Assessment Center we have the option of Audit how the different courses are been given for different teachers. We have 12 groups of the same subject (marketing) in each semester so we have 5 or 6 teachers, with different styles. So I work in the project of following the implementation and an evaluation of the course of Marketing in Lotus Notes –Learning Space (LN-LS). This project began in the semester August-December 2000, and in the semester January-May 2001. As I am the designer (author) of the course of Marketing, I have access to all the database generated in our server for the different groups. First I built a matrix like the following:

TEACHER	**Status**	**Groups**	**Students number**	**Time using the course**

The expectations was that an experienced teacher has less problems in the use of the course in learning space. Second I built another Matrix with the following elements:

Activity	**Group 01**	**Group 02**	**Group 03**	**Group 04**	**Etc.**	**Etc,.**
AdvertisingTopic 1						
Ethical dilemma Topic 1						
EXAM Topic 1						
Advertising Topic 2						
Ethical DilemmaTopic 2						
etcetera						

Third, so in the Assessment Center I found the report of how many of the different activities were graded, and I filled the matrix with the number. After that I compared the number of students with the number of activities grades, and I found the deviation. If the difference is low, it is possible that some students didn't do the activities, this is acceptable. But if we found that the difference is big, so we have a problem. And we suggest actions to do with the teacher that have problems. If the problem is lack of abilities to work with learning space we suggest taking a course in the use of learning space. We make a following for the next semester, so we expect that the differences will be lower each time the teacher use the LN-LS course. Of course we understand that learning is difficult to standardize, but we also think we can offer a better service (education) using the advantages of on-line courses.

Conclusions

The use of the Assessment Center is very useful as an active and quickest way of receive and grade the activities the student make. And also we can control the performance from different teachers in our model called "redesign".

The WWW, ADDIE, and the ADL Guidelines

Abstract

The proliferation on online learning requires that instructional designers know and apply sound instructional design. How and where they locate guidelines for ready reference has been addressed by the Joint ADL Co-Lab that provides *Design Guidelines for the Development and Evaluation of Effective Web-based Instruction.* To provide appropriate illustrations of the guidelines and ready access to them, the authors have created a Web site that illustrates the ADDIE model of instructional system design along with a repository of guideline examples.

The increasing development of Web-based learning necessitates careful and well-designed learning environments. The proliferation of organizations and institutions offering and often requiring online learning (Aldrich, 2001; NCES, 1999; Salopek, 1998; Fjortoft, 1995) means instructional designers must not only understand effective site design but also design that supports instructional interactivity. In response to the need for principles that inform designers, the Joint Advanced Distributed Learning (ADL) Co-lab in conjunction with the Institute of Simulation Training in Orlando, Florida researched effective practices and created the *Design Guidelines for the Development and Evaluation of Effective Web-based Instruction*. The ADL Initiative "is a collaborative effort between government, industry and academia to establish a new distributed learning environment that permits the interoperability of learning tools and course content on a global scale. ADL's vision is to provide access to the highest quality education and training, tailored to individual needs, delivered cost-effectively anywhere, anytime" (Joint ADL Co-Lab, 2002).

The Joint ADL Co-Lab envisions the guidelines as part of a dynamic and evolving resource to which instructional designers, researchers, theorists, and students may contribute. The current guidelines were completed in 2001 and made available to the public as a downloadable document, available from http://www.adlnet.org/ADLDOCS/Document/guidelines.doc. The design guidelines are organized into the following topics.

- Instructional Content Design
- Multimedia Design
- Web Site Design
- Graphic Design
- Web Page Style
- Web Page Layout
- Web Usability

There has been a concern within the ADL community that instructional designers may not reference the ADL guidelines (Hall, 1997) throughout the development process of Web-based learning. While the guidelines are comprehensive (over 80 pages) illustrations are limited and few. Additionally, there are concerns that designers may rely more on fast-prototyping rather than follow an instructional systems design approach (ISD), such as ADDIE, to material development. There is also a question as to how the ADL guidelines fit into the ISD process.

In response to these concerns, the authors proposed and developed a Web site for instructional designers of Web-based learning tools or environments that serves two functions:

> (a) provide a general overview of the ADDIE model of Instructional Systems Design (ISD) and
> (b) allow instructional designers to locate design strategies that will improve the educational functions of Re-useable Learning Objects (RLOs).

The site provides an overview of the ADDIE model of instructional design. Users can review the model and find general tips by stage or they can search a database to identify specific, research-based applications of effective design. For example, if a user wanted to find some different ways to provide interface interactivity, he or she could search the database and view examples of specific applications.

Due to the depth and breadth of the existing guidelines, the site designers reviewed and re-organized the guidelines based on the input of experts. The site design initially came from feedback from the same experts who felt that instructional designers had preferences in how the guidelines should be presented. There are two paths in the site. The first allows the user to review the ADDIE model and, from some sub-tasks, provides links to examples of a step. The second path leads to the ADL guidelines which are organized into four categories: Re-useable Learning Objects, Instructional Design, Multimedia Design, and Web Site Design. Each category lists sub-categories through which visitors can view sequentially or randomly. Each category and sub-category are designed to show an example that illustrates a specific guideline. Not all guidelines have an associated illustration. Visitors will be able to submit an example (either as a hyperlink or an asset) which will be reviewed for suitability. If accepted the example will be posted to the repository with credit cited. Several institutions will require graduate students in instructional technology to submit either objects or new guidelines. It is the intention of the site owners to update and revise the ADL guidelines as they become obsolete or irrelevant as new technologies and methods of instruction.evolve.

The site has been designed to supplement formal university courses, training, or self-study. Students or professionals may have been trained in instructional design but they may not have seen examples of good practice. This site is not a tutorial but rather a device that will allow learners and practioners at various stages of understanding and experience to find illustrations of basic principles, tips for completion of each step, and practical applications that can be used immediately. Although the site is designed for those interested developing Web-based learning contents, the principles and concepts represented here provide a basic introduction for any ISD project.

Abstract: This paper explores the approach used by university students from one of the local University in Malaysia in designing and developing courseware (online or CD-ROM) for teaching and learning purposes. Exploratory studies from the final year students project documentation were carried out to examine the main courseware development technique process used among the university students. Findings indicate that majority of the university students comply with all the main courseware development techniques process requirements such as feasibilities studies, designing phase, implementation phase and testing phase except on the milestones, users manual, system manual, operational and maintenance manuals of their system. To produce a marketable courseware product for teaching and learning, it is very important that a developer should fulfill all the standards in designing and developing a new courseware besides satisfying the users' needs.

Introduction

In general, according to Learning Circuits (2002), "e-learning" "covers a wide set of applications and processes such as Web-base learning, computer-based training, virtual classrooms, and digital collaboration. It includes the delivery of content via Internet, intranet/extranet (LAN/WAN), audio and videotape, satellite broadcast, interactive TV, and CD-ROM". As "e-learning" is crucial to the development of Malaysian society; its potential can only be realized if high quality content is readily available at the right place, the right time and the right price. To fulfill such needs and high quality standards, most government-backed institutes of higher learning (IPTA) in Malaysia are encouraging their students in the field of Multimedia Technology to create quality "e-learning" courseware that can fulfill the needs of their target groups. The main purpose here is to expand local expertise in "e-learning" (users, designer and developers) in line with the new NITC strategic plan (NITC, 2001) to develop the relatively new spheres of 'E-Community', 'E-Public Services', 'E-Learning', 'E-Economy' and 'E-Sovereignty'. Therefore, a case study were carried out to investigate the strategy employed by university students from Multimedia Technology program in one of the local university in Malaysia in developing courseware on-line or CD-ROM. This paper will focus on the process and strategy used among the students in designing and developing new courseware that comprises multimedia components (text, graphics, animation, simulation, audio and video) – (Learnframe, 2001). The courseware developed can then be accessed through the Internet, Intranet or CD-ROM.

The Study

Exploratory study from the final year project documentation, only 18 out of 60 (almost one third) final year students chose to design and develop a new courseware as their final year project to be used by target groups such as school children, members of the public or other university students. However, only 5 out of 18 students choose to develop both on-line courseware through the Internet and CD-ROMs, while others preferred using CD-ROMs. This is due to the fact that CD-ROM can accommodate more and bigger multimedia files, thus adding to its interactive value as well as its attractiveness. Besides, CD-ROMs are portable and do not require connection to the Internet therefore allowing for a faster response compared to on-line access to learning materials where too many multimedia elements will slow down the on-line courseware downloading time.

BEST COPY AVAILABLE

Findings

From the case study, the standard methods used by the students are:

- Feasibilities studies on gathering user requirement through data collection (questionnaires, interviews, observations and other sources), technical, economic and operational aspects in developing the new courseware;
- Designing phase: structure chart which consists of system flow chart or pseudo-code, hierarchical chart or sequential chart and storyboard; and System User Interface
- Implementation phase: Creating the Tables / Databases needs (normally for on-line courseware for user login); creating the system user interface; and creating the coding (will need to include security and system coding for on-line "e-learning").
- Testing phase – executing a program with the intent of finding an error and verifying that the system meets all the requirements as set in the system design specification. The four types of testing are: unit testing, integration testing, validation testing (Alpha testing and Beta testing) and system testing.

In this case study, of all eighteen (18) projects documentations by the final year students, only three (3) students fulfilled all the development process requirements, while others are unable to finished the Beta testing and System testing phase. Only 13 students describe the functional components of their system in detailed. By comparing the student development process as to the software engineering process stated by Sommerville (2000), it was found that, all students does not include milestones, users manual, system manual, operational and maintenance manuals of their system.

Conclusions

From the exploratory study of the final year project (project documentation and courseware produce), majority of the university students comply with all the main courseware development techniques process requirements such as feasibilities studies, designing phase, implementation phase and testing phase except on the milestones, users manual, system manual, operational and maintenance manuals of their system. As maintenance phase is very crucial, therefore all university students should be alerted with the importance of milestones, users manual, system manual, operational and maintenance manuals in their system. Besides, as a developer, the students should also be sensitive to their users' needs rather than basing courseware content needs on their own preconceived notions (David, 2002; Anne, 2002).

In conclusion, a student will be able to produce a marketable new courseware (on-line or CD-ROM) if that courseware had been developed according to the standards in the courseware development processes as well as satisfying the users' needs. As a result, the courseware will easily allow for 'mastery of content' as well as 'mastery of learning'.

Proposal Summary of "Shaping the Delivery of Middle School Mathematics Curriculum through Production of Original Video"

1. Overview - Objectives

Participants will:

- Walk through the process experienced by an expert panel of Texas Middle School Teachers that was used to create real world scenarios that are mathematically rich and used as the basis of creating PBS-quality video
- receive information on a proven process that has been successful for districts receiving millions in technology awards; used by a consortium of 6 school districts to build a technology rich middle school mathematics curriculum that is standards based;
- articulate the process of consortium building and developmental stages of "break-through thinking" in designing a customized multi-media, Internet delivered curriculum for diverse student populations for middle school mathematics
- have information as how to access the eMath Project with 30 math modules as funded by a $1.8 million TIE Grant from the Texas Education Agency; how to participate in on-going research of the impact of emerging technology in mathematics education
- view and interact with Professional Development module and experience one student module with its interactive, video, gaming components
- experience one teacher's journey in break-through thinking on developing the mathematics modules for grades 6-8

2. Outline of Presentation
   - Review 3 years of planning, goal setting, defining needs by 6 school districts
   - Discussion of teacher input, curriculum design, break-through thinking in process of designing the curriculum;
   - Outline of the design of the web-based content to support the original video clips used in the modules with a thematic and problems based approach
   - Experience sequences of the video that are teen-interest based on problems that both this age group and society must use mathematics

   Audience will experience photos of teachers in the development process, see examples of modules that teachers have developed, view a video clips of administrators discussing the support given to the project; experience a module (as though they are students) to solve the posed problem and work toward solutions with web-based and video sequences.

3. Research Based — Because this project is cutting edge of emerging technology curriculum development, an Expert Panel of nationally known math professors was engaged through TEXAS A&M University to write a 'White Paper" on best practices in middle school technology initiatives in mathematics. The research is embedded in a staff development module.

4. Presenter Qualifications—In past 9 years has received funds for nearly $22 million for technology initiatives for consortiums of Texas schools, all the while serving as assistant superintendent for curriculum or acting as project director. Served on the 1999-01 Texas Education Agency Educational Technology Advisory Committee.

    - Workshop appropriate because it represents a major effort to integrate emerging technologies including a major use of original video into the middle school math program; uses teacher expertise in designing the content and delivery system
    - Major Presenter has given presentations to local, state, national, international audiences on technology, school reform, staff development for past 15 years

The Development of a Web-based Teaching System for Traffic Engineering Education

Leonimer Flávio de Melo and Luís Geraldo P. Meloni
Faculdade de Engenharia Elétrica e de Computação
Universidade Estadual de Campinas
Brazil
{leonimer, meloni}@decom.fee.unicamp.br

Abstract: This paper presents a teaching and learning environment for use in telephony courses in Electrical Engineering, where computers and Internet are meant to be used as facilitating tools for distance learning and attendance classes. The system uses client-server architecture, integrated with the Matlab software, allowing the conception of simulators, which offer high interactivity for the students. The simulators show the numerical results by means of graphics and tables. The system may also be used by professionals of traffic engineering.

Introduction

The teaching and learning of traffic engineering are in many aspects a hard task, as it involves topics with quite complex statistical computations. Besides the conventional methods for Internet courses based on HTML pages, the developed system is strongly supported by simulators, bringing to the students a high level of interactivity. The input pages for the simulators are called by hyperlinks strategically positioned inside the topics of study. These simulation pages may also be called in exercise resolutions, representing a very helpful tool for the students. For implementation of the simulators, the Matlab server was integrated by associating the computation power of this software with the high accessibility of the Internet. Matlab is well known by the academic community, offering a great number of mathematical functions, area-specific toolboxes and an ease programming language. In this Web course, we have developed a simulator for the classical traffic engineering equations. The interactive visual environment makes available a large variety of possible results for the students, illustrative graphics and tables. The system, accessible by the Web, can be used in distance learning classes, as well as in attendance classes. The software may also be used in professional traffic engineering computations, replacing with advantages the use of graphics and tables in the paper form.

System structure

The system uses the client-server architecture, rendering availability to the course pages and the simulator calculations over the Internet. The input-data pages, programmed in HTML, are loaded in the user's browser. The data are submitted to HTTP server, using the CGI (*Common Gateway Interface*) standard, allowing the received data to be processed by Matlab. The Matlab in response generates the numeric results, tables and graphics. These data are structured and sent back to client as an HTML page format, as shown in Figure 1. By the use of TCP/IP protocol, the system may also be accessed in a private network (Intranet) or the Internet. The Matlab Web is a multithreaded server, managing the communication between the Web application and the Matlab itself and also controlling the user accesses to the system.

Functions and visual interface

The traffic engineering Web-based teaching system covers loss systems and delay systems modeling. The course was developed with emphasis in the pedagogical aspects, emphasizing more the easier

BEST COPY AVAILABLE

understanding of the subject than the rigorous mathematical treatment. It provides demonstration of the most used equations in traffic analysis, explains in details the theory and also proposes several exercises that the student may solve by the use of the simulator.

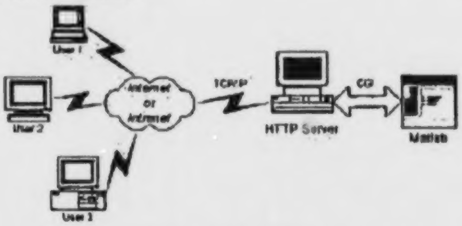

Figure 1: System structure

The main routines of the traffic-equation simulator are the Erlang B formula, for loss or blocking systems, and the Erlang C formula, for delay systems. Figure 2 illustrates a returned page for loss systems. The student defines two among three possible variables: number of channels, traffic intensity and blocking probability; he must also define the desired output. The simulator returns the numerical results, in this case the blocking probability, as well as graphics for the traffic intensity and for the blocking probability. These graphics displays several curves around the desired output. This is a very useful visual feedback for the students. The simulator also generates a table showing the traffic intensity versus the blocking probability and the number of channels. For the professional applications in traffic computations, the system is very attractive allowing the search of the desired results in an easier way than the traditional method of table consulting.

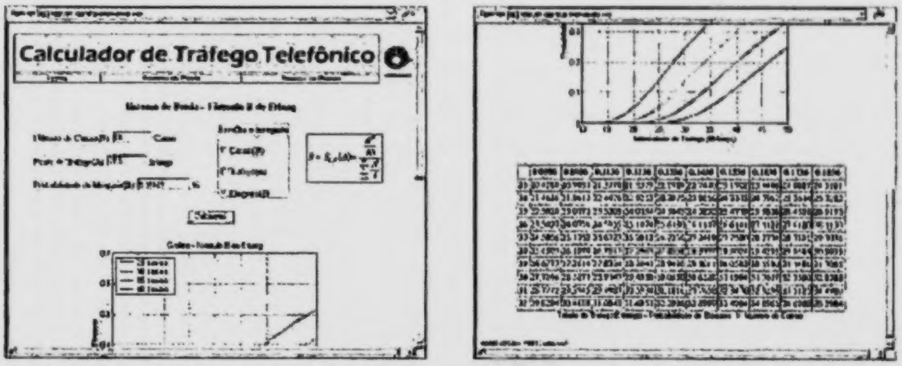

Figure 2: Final page for loss systems

Conclusion

The development of a system using Internet access associated with a powerful mathematical software, such as Matlab, brings a nice solution for telephony traffic teaching and learning, well adapted to distance education systems. The system may also be used as support tool in attendance classes or even in the corporative environment for traffic engineering analysis. It is important to emphasize that with a simple HTML programming, the system may be easily adapted to other content courses using simulations in the Matlab. The use of the simulators offers to the student a high level of interactivity, more attractive than the traditional reference books on the subject of traffic engineering.

Tennessee Board of Regents
Regents Online Degree Programs

Tennessee Board of Regents' colleges, universities, and technology centers joined in Fall 2001, to offer the **Regents Online Degree Programs (RODP)**. All the institutions are fully accredited. All thirteen TBR two-year colleges deliver and award the noted associate degrees, while all six TBR universities deliver and award the noted bachelor degrees. Courses completed in the Regents Online Degree Programs are entirely online and transferable among all the participating institutions. Students are able to choose the college or university (home school) for their admission, registration, and the award of their degree.
The degrees offered are:

- Associate of Applied Science in Professional Studies: Concentration in Information Technology
- Associate of Arts in General Studies (University Parallel)
- Associate of Science in General Studies (University Parallel)
- Bachelor of Professional Studies with concentrations in Information Technology or Organizational Leadership
- Bachelor of Interdisciplinary Studies (General Studies/Liberal Studies/University Studies)
- Masters in Education (in development for Fall 2002)
- Certificate in Computers Operations Technology (TN. Technology Centers Fall 2002)

The Regents Online Faculty and Staff have been highly trained in teaching, learning, and assessing the needs of online students. The Regents Online Courses are designed for a 12 week semester–in an interactive, asynchronous (accessing courses at your convenience) format. These courses contain the same content and rigor as courses on campus. Student Services such as advising, library services, student support, and other forms of student assistance are offered for online delivery. Technical support for accessing course lessons and assignments are available 24 hours 7 days per week.

> Vision: "A better life for Tennesseans through education"
>
> Mission: "The Regents Online Degree Programs, using technology, will improve access to high quality, affordable, student-centered learning opportunities through cooperation among TBR institutions."

Goals:
To increase access to higher education for adult Tennesseans, especially those with some college experience. Census data document that Tennesseans lag behind both the national and regional averages of educational attainment. Further, attainment is uneven across the state, with rural areas lagging far behind urban areas. Economic development of the state depends on increasing the skill levels of the population.

To maximize the effective use of technology for delivery of college-level instruction. Distance delivery through the use of technology will increase access to higher education, especially in remote areas of the state and for adult learners for whom time flexibility is a critical resource.

To provide student access to web-based courses and degree programs. Web-based courses will reach populations not currently enrolled in higher education, and will also permit students who are currently enrolled in on-campus courses to take additional courses, thus completing their programs sooner.

Partnership with Eduprise E-learning Corporation

Eduprise, the leading provider of enterprise e-Learning services for education institutions and businesses, partnered with Eduprise to provide strategic planning, infrastructure hosting support and instructional development services. Eduprise established a major role in TBR's bold initiative by providing the infrastructure support services to underpin the strategic plan for the Regents' web-based degrees. These services include a hosted WebCT course management system, 24x7 technical help desk for students and instructors, WebCT software training for instructors, instructional design assistance.

Current Success

It was projected that the Fall 2001 enrollment would total to 300. However, the final enrollment number was 1,954 with a withdrawal rate of less than 12% and a dropout rate of less than 20% compared to the national average of 42%. The student and faculty surveys indicated an overall satisfaction rate of 79%. The Spring 2002 registration ended at 3,663 enrollments, far exceeding, the Fall 2001 numbers and an increase of over 80%.

If this proposal is accepted, the participants will receive data regarding the program, student, and faculty evaluations, retention rates, and program evaluation which indicates a 84% student satisfaction rate.

The Use of Relational Blocks Demonstrated

Linda L. Merillat
Department of Education
Washburn University
Topeka, KS
United States
lindam@inf-o.com

Dr. Anne Daugherty
Baker University
Baldwin City, KS
United States
adaugherty@bakeru.edu

Abstract: This demonstration will give conference participants an opportunity to see, work with and experience these newly designed manipulative tools, or relational blocks. A quasi-experimental study explored the effects of using these relational blocks to better teach pre-certification teachers basic relational database concepts. The three-week study was conducted with two classes and included a total of 37 students. One class used relational blocks while the other class used note cards. The remaining database concept material was the same for the two different classes. Class A, the control group, had an average pre-test score of 9.9 out of 50 and a post-test score of 27.7. Class B, the experimental group, had an average pre-test score of 16.4 and a post-test score of 34.3. Using ANCOVA, an F value of 28.7 was obtained which is significant at the .01 level.

Introduction

Beginning as young children, human beings strive to put order into their chaotic existence by continually organizing, generalizing, sorting, and categorizing the things in their world. Mathematics is one tool we use to help organize this information. With technology, databases are another practical tool we use to help maintain this same order. The underlying principles of a relational database are very abstract, mathematical constructs.

In many cases, children begin to use mathematical concepts intuitively. "They can generalize by touch and physical perception long before they know the words for the generalizations they form." (Rudolph, 1984) A child understands "round" versus "triangle" versus "square" before they can name those shapes. The benefit of using manipulative objects in teaching abstract mathematical concepts has been documented for several years. Cuisinaire rods, and other manipulative tools, are very popular in many school districts and are included in many of those district's educational standards. (JCPS, 2002; GASD, 2002; SCCROE) The use of manipulative tools is not limited to just pre-literate students, either. The standards that use Cuisinaire rods in these school districts cover a range of age groups from kindergarten through elementary school. Would introducing the abstract concepts of relational databases to children or individuals at this same level allow for the student to develop or form intuitive understandings of these abstract mathematical concepts at a non-verbal level? In doing so, would the student be better able to apply these concepts in practical ways? Relational blocks provide a visual, concrete way for students to access these abstract concepts.

The Study

A quasi-experimental study was conducted to test the usefulness of relational blocks. The basis for evaluation for the students in the study was a pre-test and a post-test and included three weeks of instruction on basic concepts of relational databases. The tests covered the essential concepts presented on relational databases. The test was developed by the researcher for this study and can be accessed on-line at http://www.inf-o.com/ RelationalBlocks.

The key operational variable is the use of relational blocks. Relational blocks are specially designed blocks that can be manually manipulated by a student or groups of students. The relational blocks provide tactile representations to the abstract database concepts of a database table, a row, an attribute, and the relationships between these objects.

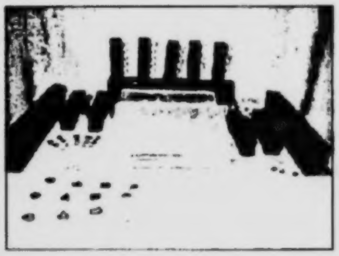

Figure 1 - Relational Blocks Materials

A database table is represented by a rectangular shaped open box. Each row within a table is represented by a block that is stood upright within the table, or box. The boxes and blocks, or tables and rows, and color coded. Each block or row has several hooks attached to it. These hooks represent attributes or columns within the row. The table and each row are identified with a label that fits within slots on the front of the box. The attributes or columns within a row are identified with additional labels that are affixed to the block with a rubber band.

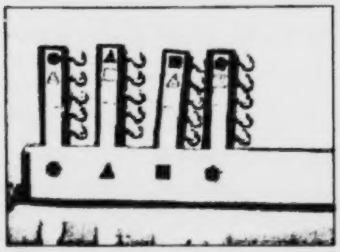

Figure 2 - Blocks for Tables and Rows

Relationships between the data within the tables and rows are illustrated by connecting the hook from one data value to the corresponding data value in another table by using a plastic string with two washers attached to the ends.

The use of relational blocks consists of performing a series of exercises designed to show how data in a relational database is stored and manipulated. During the initial introductory class, the experimental group completed three exercises using the relational blocks. The first one was a simple, abstract exercise; the second one was a conceptual exercise, and the third one was a technically complete exercise. The exercises used can be accessed at http://www.inf-o.com/RelationalBlocks.

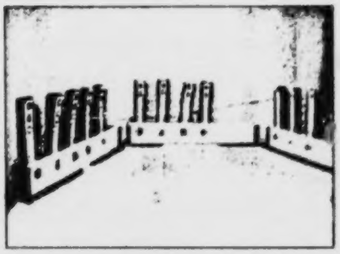

Figure 3 - Visualization of Relationships

Findings

An analysis of the pre-test and the post-test scores revealed these results:

Source	SSadj	df	Msadj	F
Adj	183.0	1	183.026	28.7
Adj Within	351	27	6.4	
Total	534.2			

The obtained F value of 28.7 exceeds 7.72; consequently, we can conclude that the post-test score results were significant at the .01 level.

Conclusions

In summary, the results of the study were encouraging. The results of the post-test were significant and simple observation would indicate that using the relational blocks were beneficial in laying a conceptual framework for the students before introducing the abstract concepts of relational databases. However, because of the small sample size, and because of the vastly different temperaments of the two class sections, more research is needed before firmly establishing the benefit of using relational blocks in teaching the concepts of relational databases.

Creating Virtual Experiments within a Web-based Adventure Game

Leslie M. Miller,
Rice University
Center for Technology in Teaching and Learning
United States
lmm@rice.edu

Abstract: Can students learn the process of experimentation and scientific method though virtual experiments within a game environment? This was a central goal of a web adventure series, The Reconstructors™. Using Macromedia's Flash 5.0 and an engaging narrative, the web adventure was tested in middle school classrooms.

The web site (http://reconstructors.rice.edu) is part of a project funded by the National Institute on Drug Abuse. The content focus of this effort is the history and biological impact of a class of drugs known as opioids. The benefits and challenges of using this type of approach for teaching sophisticated science concepts to middle school students is described in this pap er.

Pedagogical Foundations

The Internet's unique capabilities offer a certain seductive aspect that engages people of all ages. Not all of the Internet's applications could be said to have high educational value. Yet, from our own research on adolescents' media habits and preference, we find that "playing games" is high on the priority list of how they use computers (Miller, Schweingruber & Brandenburg, 2001). On the educational side of the equation, however, the Internet provides support for new instructional approaches, such as cooperative learning with other learners at a distance, demonstrations, online references, powerful simulations, tips, tutorials, and wizards (Carliner, 1998). Our efforts are directed toward blending the excitement of games with compelling science content to "create interesting, realistic contexts that encourage the active construction of knowledge by learners" (CTGV, 1993, p. 52). The work of John Bransford and the Cognition & Technology Group at Vanderbilt (CTGV) pioneered the way for exploiting the power of technology to achieve serious instructional goals.

The pedagogical strategies of situated learning (Brown, Collins and Duguid, 1989) or anchored instruction (CTVG, 1993) can provide the prerequisite framework on which to build multimedia environments that have significant learning outcomes. The task of blending best practice in education with the bells and whistles of multimedia is challenging. Perhaps that is why it is more common to find multimedia, particularly on the web that is rich in technique, but shallow in content. The use of technology for technology's sake rather than wrapping technology around tried and true learning principles is a common pitfall.

Specific Example

In the specific project that was designed and field tested, a student enters a futuristic world in which he or she assumes the role of a "Reconstructor" charged with re-discovering medical knowledge from the past. The five episodes – Plaguing Problem, Ancient Alarm, Analgesic Anxiety, Mystery of Morpheus, and Alpha and Omega – carry the concepts and narrative forward. Over the course of the episodes, players "solve the problem" while learning about concepts such as neurotransmission, the neurobiology and history underlying drug addiction, pain management, and analgesia.

Sample segments of the game with virtual experimentation will be presented at the poster session. For example, a major focus of one of the Episodes is to lead players through the same reasoning and experimentation that was performed by Otto Loewi to discover the chemical transmission of nerve impulses. He won the Novel Prize for Medicine in 1936 for this groundbreaking work. His experiment used frog hearts. The same experiment is repeated by the player within the story line of the game and he/she is asked to draw conclusions.

This, along with other examples of experiments which students would never be able to conduct in classrooms, is possible via Flash and the web. The comments received from end-users suggest that the web site has drawn the attention of students of all ages to investigate topics that may not normally be tremendous attention grabbers. Yet, crafted within the game environment and built around solid educational strategies, the site has proven efficacious in both gaining screen time and teaching difficult topics. Another paper presents the results of pre and posttest field test results with middle school students. Significant gains were made in specific knowledge concepts for students of all socio-economic status groups and for both genders. (Miller, Schweingruber, Oliver, Mayes and Smith, 2002).

Summary

Bruner's (1996) advocacy of narrative as an effective pedagogical approach in science education coupled with the "problem-solving" characteristics of CTVG early work in multimedia were used to produce a web adventure series with substantive science content within an engaging computer world. This process and the inclusion of virtual experiments helped to generate an adventure series that has been commended by several educational organizations.

Development of XML-Based Chinese-Multilingual Two-Way Dictionary for Electronic Textbook

Ming Yin, Shinichi Fujita, Satoshi Kasihara, Hiroaki Hasiguti, Seinosuke Narita
Narita Laboratory, Graduate School of Science and Engineering of Waseda University, Japan
yin@narita.elec.waseda.ac.jp

Abstract: This paper discussed how to design a comprehensive and intuitive Chinese-multilingual two-way electronic dictionary for an electronic textbook. The bi-directional electronic dictionary has made the definition search between Chinese and other language words easier. An XML document is created to store the multilingual resources under the support of Unicode. This paper has realized the display of multilingual characters in one homepage. The pinyin of Chinese characters can be shown correctly. The proposed method may not only regard Chinese dictionary, but may be useful for other electronic dictionary design.

Introduction

Along with the development of computer technology, the various electronic dictionaries are developed and put into the actual application such as English-Chinese dictionary. But when a web-based Chinese dictionary is designed, it must be considered that the learners may come from different countries. For a Japanese, Japanese will be displayed but for an American, English will be displayed in same web page besides Chinese characters. Therefore in some Chinese textbooks, multilingual explanation of Chinese is provided such as English, Japanese. But it is impossible to enumerate all languages for the limit of textbook. The electronic dictionary may achieve to add a new language or add a new word anytime. So it is necessary for a web-based Chinese dictionary to support multilingual display.

Choosing Character Encoding

For a web site of Chinese-multilingual dictionary, it will display two languages characters on a web page. A single language cannot simply be declared on the whole page, for instance, if Chinese is declared, then the Japanese text will be misinterpreted. So this paper declared UTF-8 which supports many languages as character encoding to format all pages. UTF-8 is a subset of Unicode and is a commonly used code page on the Web. In UTF-8, each 16-bit Unicode character is encoded as a sequence of one, two, or three 8-bit bytes, depending on the value of the character. When the web server retrieves data from XML documnet, the data can be written out to the browser as UTF-8 and displayed correctly.

Display pinyin of Chinese characters

Because the pinyin of Chinese characters has unusual appearance, it is unable to replace with the characters in windows, therefore this paper uses images to display pinyin correctly. Every character in pinyin with only one index value corresponds to an image which express the appearance of the character. The pinyin will be displayed as images by transforming a series of index value to its corresponding images. For example, the pinyin of Chinese character "语言" (meaning language) is , among them, the and can not be expressed by any characters in windows. When using images to express pinyin, the index value of is y0u1y0a1n0, here y0 corresponds one image whose content is y,u1 corresponds another image whose content is u, and is same to a1 and n0. Through the index value y0u1y0a1n0, the correspondent images can be found. The pinyin can be expressed by those images.

Index value	Image
y0	y
a1	ā
u1	ū

Format of XML Document in Dictionary

This paper uses XML(eXtensible Markup Language) document to store datum of the dictionary. XML can be encoded using almost any character set including UTF-8(Unicode). In order to support multilingual characters, this paper selects UTF-8 as character encoding. XML documents can be edited using any text editor such as notepad. It is also possible to create XML document by program. The <dictionary> is set as root element and the main tag is <word>. The tag <chinese> holds Chinese word. The <mean_language> is a tag to hold the explanation of the Chinese word in a language here language expresses the actual language name such as English or Japanese for example the tag < mean_Japanese> holds the meaning of Chinese word in Japanese. The tag <pinyin> holds the pinyin characters which are consisted of image's index value. The XML document is shown as follows.

Add elements to XML Document

For a new Chinese word, it must be inserted to the XML document including the character, meaning of every languages and the index value of pinyin. But when adding the explanation of a new language to existed Chinese word, the tag of correspondent language and text will be inserted. In both two situations above, one way is editing the XML document directly using text editor, the other is editing the XML document through program. Because XML is very simple, it is not difficult to edit XML document directly.

Retrieval of Dictionary

Retrieval Using Chinese Characters

This retrieval way will search the Chinese characters in XML document which the learner inputs. According to the learner's preferred language of browser, the retrieval result will return the describes of Chinese character meaning in correspondent language and display them in web page.

Fuzzy Retrieval Using Pinyin

When the learner can not input the Chinese characters correctly, it is possible to retrieve the characters using pinyin. This time the pinyin which input by the learner does not contain the corresponding four tones of Chinese characters, the retrieval way is called fuzzy retrieval. For example, the yuyan can be input for retrieving the characters. But the retrieval result will return all the Chinese characters which hold the same pinyin as yuyan(not include tones) in XML document. The learner can find the characters in the result list.

Reverse Retrieval

When the learner does not know the Chinese characters, it is impossible to input the Chinese characters or pinyin. Under this situation, the learner can input the meaning of the Chinese characters in his own language.

Pronunciation Based on TTS(Text-to-Speech)

TTS is the ability of the operating system to play back printed text as spoken words. This paper selects the Microsoft's Speech API(SAPI) to convert the Chinese characters into speech. This enables learners to know the pronunciation of the Chinese characters.

Discussion

Realization of multi-languages support has more other factors to be considered. When an electronic dictionary is designed, it is very important that good design is useful both for the user and the developer.

Distance Education as a Discursive Practice: Voice, Discourse and Pedagogy

Ananda Mitra, Ph.D.
Wake Forest University
Department of Communication
Winston-Salem, NC 27109
ananda@wfu.edu

Abstract: Distance education has taken on a new shape with the introduction of new digital technologies that have made the process of interaction between the teacher and student a far more vibrant process. Using the construct of "voice" this paper argues that the role of the teacher and the student is constantly changing as multiple voices can be heard in the discursive pedagogic space of distance education.

Introduction

The idea of voice, when applied to the process of technology-assisted distance education, begs the question of whose voices can be heard in this space? For an institution to be able to claim successful networking, it must allow the free flow of communication between the various elements that are networked (Sproull & Kiesler, 1992). The new climate of distance education provides such a networked environment where the players can claim to operate within a networked education organization. Robust and efficient technological opportunities make it possible to create a unique pedagogic discourse, and a teaching discursive space, where the teachers and students can take up roles that are different from traditional classroom roles.

Implications of thinking of Voice

Research on interpersonal communication, communication apprehension, and the opportunities provided by digital communication has demonstrated that, first, more voices can be heard on synchronous (and asynchronous) educational communication tools such as teaching chat rooms (Walther, 1996). Thus, in answer to the question of whose voices can be heard, it is safe to suggest that the students' voices are the ones that are most conspicuous when technology is applied to the distance-learning (or even traditional learning) scenario. This tendency can also be traced in the case of asynchronous communication tools with potential distance-learning applications. Using a tool such as e-mail to communicate with the instructor is often accompanied by an increasing burden on the teacher to respond to all the electronic letters that arrive with missives and voices of the students who are often the quiet ones in the classroom. The reason for this phenomenon can be traced within the literature on communication apprehension, but the consequences of this phenomenon within the context of digital learning with enhanced technology is the focus of attention in this paper.

To start with, the possibility offered by the new technologies can lead to a condition where many of the participants in the pedagogic arena are able to speak together. For instance, in a chat room class the students and the teachers are all able to speak together and can engage in a discussion around an issue that might have been treated as "lecture" material in the traditional classroom either in the face-to-face situation or in a video-enhanced distance-learning environment. The digital option, however, offers the opportunity to all participants to interact in real time. Since this technology often helps to overcome communication anxieties, it is also often the case that, independent of location, more people can actually participate in the discussions. To be sure, such a phenomenon can lead to conditions where the discussion can become unwieldy, given the fact that many more people participate in the discussion. Most research on chat room environments indicates that the lurking habit is insignificant in the synchronous chat room as compared to the asynchronous list services and Usenet bulletin boards. Consequently, a Babel of voices can be heard in the chat room. Yet such a collection of voices demonstrates that more agents are using the opportunity provided by the technology to utter their point of view using their own voice instead of either being silent or having some one else speak for them. In this new pedagogic space, the very act of utterance becomes a determinate moment, since it demonstrates that anyone has the right and ability to speak in this geographically distributed classroom and that location and status could disappear in the nonhierarchical teaching situation (Mitra, Chesner, Burg, and Ferebee, 2000).

Indeed, the shift from being spoken for by a class representative or even by the teacher could disappear in the technology-enhanced distance-learning environment where traditional determinants of speaking capital are removed. In the past, with video technology, the teacher would have a group of students in a face-to-face classroom and a different set of students in the distant classroom. Often the physical proximity to the teacher and the easier interactivity offered in the face-to-face classroom gave those students a certain advantage in gaining the teacher's attention. However, the digital classroom removes such biases, since in cyberspace the teacher and all the students are equidistant from one another, and no particular voice has any advantage based on geographic placement. This is true both for synchronous and asynchronous distance-learning technologies. It can be argued that in the asynchronous technologies that use electronic mail or Web-based tools, every voice is equitably placed in terms of distance. Indeed, the classroom in such cases becomes "ageographic," since the presence of the other students and teachers are felt in the voices and texts that appear on the ubiquitous computer screen of the student and the teacher. Here, momentarily, the technology of the computer erases the traditional relationships between voice and physical location, giving each player an equal voice.

This egalitarianism is also related to the way in which the teacher can exercise control in allowing or disallowing certain voices to be heard. As suggested earlier, the power attached to the teacher has often been the result of the physical structure of the classroom. In the case of distance-learning environments, where teachers would be teaching before a video camera and the students would be watching a television monitor, the teacher takes on the role of the narrator and the teacher's voice necessarily becomes more powerful. The teacher becomes the authoritative voice that is broadcast over closed-circuit television or by videotapes sent to students. However, in the digital situation, such technological and spatial advantages do not exist and the teacher often has fewer tools available to control the flow of the discourse. The natural advantage attached to spatial arrangement is lost, but the teacher and the students are required to mobilize their discursive strategies to assure their voices are heard. Indeed, within a distance- learning scenario where the teacher does not occupy a predefined position of power, it is possible that, instead of being a teacher, the person has to become a moderator to control the flow of the discourse rather than supervise who has a voice in that discourse. When considering the pedagogic condition from the perspective of voice, it becomes clear that the role of the teacher in the discursive environment changes, since it is the voice that becomes more important than a presence that is dependent on pre-existing power vectors. In the electronic distance-learning classroom, the speaking capital determines the teaching process rather than the capital attached to other determinants such as school year, teacher status, or even the physical set up of the classroom.

That voice can be considered central in thinking about the new technology also opens up the opportunity to consider the new pedagogic space primarily as a discursive space where the centrality of discourse and dialog is emphasized. As mentioned earlier, the teaching process is more acutely a discursive act in contemporary distance education. The distance-learning classroom now becomes a discursive space and the way in which the space is constructed is dependent on the way the discourse is created and managed. With the disappearance of the traditional relations of power, the eloquence of the voices of the discursive space of the distance classroom could determine who actually "teaches." A teacher who is not eloquent could easily see his or her "authoritative voice" being usurped by a more eloquent student.

Creating a Distributed Learning Network: Forging Partnerships, Forging Ahead

James M. Monaghan
California State University, San Bernardino

In 1999, our institution was awarded a $ 2 Million, 5-year grant under the Title V program, Hispanic Serving Institutions, of the U.S. Department of Education. This grant's purpose was to improve the infrastructure of the university to allow it to better serve the 27,000 square mile region in Southern California. The intent was to create a distributed learning network, linking CSUSB to regional community colleges. Factors associated with the creation and implementation of the network have included: development of a distance learning strategic plan, development and campus approval of a distance learning policy, development of procedures for online, videoconference, and blended/hybrid course development, formation of agreements with community colleges, academic program development, assessment, authentication, student services, marketing, funding, and other administrative issues.

Key components of the grant, written by Interim Director of Distributed Learning, Susan Cooper and College of Education professor Judy Rymer, included: partnerships with ten community colleges that would offer CSUSB courses, development of multimedia resources for use in courses, and improved accessibility of the university through online web resources.

In the first two years of the grant, due to staff turnover and delays in initial startup, we rolled over a significant amount of money. In the middle of the second year, there was a one-month vacancy in the project director position (which also was the Director of Distributed Learning position). Following this time, I accepted the position as director.

With the assistance of the office of the Provost and Vice Provost and the staff of the Office of Distributed Learning, notably Dr. Rosa Gonzalez, Assistant Director, and Bill Gray, Site Coordinator, we developed a renewed plan for implementing the vision of the grant.

Due in part to limited enrollment in CSUSB courses offered at a site 200 miles from campus, we realized that it was essential to not only forge partnerships with regional community colleges that served students in far-flung locations in our service area, but to actively develop a high demand academic program that could be offered in collaboration with community college partners.

Thus, in the summer of 2001, heeding recommendations from needs assessments, we embarked on a concerted development effort to produce coursework that would lead to a Bachelor's degree in liberal studies, a degree most often pursued by prospective elementary school teachers in California. This development effort involves coordination of diverse interests in our university. Some areas of cooperation include coordination between the Academic Colleges (housed in Academic Affairs), the Office of Distributed Learning (housed in Academic Affairs), the Teaching Resource Center (housed in Academic Affairs), Academic Computing and Media (housed in Information Resources and Technology), Telecommunications and Network Services (housed in Information Resources and Technology).

Other components of the model included making registration services, academic forms, grade reporting, and other student services available through the Internet. We also stepped up our advising for potential transfer students from community colleges. Additionally, as an institution we developed dual admission agreements and agreements to offer CSUSB courses through community colleges (videoconference, live, online, blended).

With a concerted emphasis on program development, it was essential to get the campus to agree to policies and procedures for implementation of online, blended, and videoconference courses. During the spring of

2001, extensive free response surveys were conducted of key internal stakeholders on issues salient to distance learning. These surveys were then collated into categories and analyzed in summer 2001 by members of a faculty senate task force on distance learning. Members of the committee included the chair of the senate curriculum committee, the chair of the Intellectual Property Committee, the Director of Distributed Learning, the chair of the Educational Policy and Research Committee and the director of the National Center for Excellence in Distance Learning. During extensive meetings in the summer of 2001, this committee drafted a campus policy on distance learning. This policy was approved, with limited revision, by upper administration and became binding in December 2001.

Given approval of the policy, after extensive airing of the proposed policy through open forums, we were poised to accelerate development and deployment of courses. This required us to better coordinate existing offices. Thus, roles for online course development were refined between the Teaching Resource Center, Academic Computing and Media, and the Office of Distributed Learning.

In our implementation of the distributed learning network, it was essential to connect with our partner community college schools and offer a blend of coursework: online, face-to-face, hybrid, and videoconference. We also are working closely with these colleges on formal advising procedures in which community college students are encouraged to continue their education and pursue a baccalaureate degree. By working with students at a location in which they are familiar, we anticipated convincing many first generation college students that they could attain a baccalaureate degree.

To date, we have had difficulty convincing large numbers of community college partners to promote online or videoconference courses. It has been our experience that community colleges appear to desire a physical presence of the 4-year university on their campuses. Nevertheless, we have successfully conducted agreements with three new community colleges since the inception of the program.

Additionally, the campus is now actively engaged in a concerted development effort that would have been unheard of on our campus three years ago. There is a clear shift in the willingness of faculty, departments, and administration to embrace distance learning.
A new faculty senate committee is charged with continuing evaluation of courses; this will build on efforts conducted by the Teaching Resource Center and the Office of Distributed Learning.

We are currently expanding our efforts in the student services area. We are exploring remote access to personal advising, to complement a host of student services that have been implemented as a result of the grant.

We are expanding our computer network infrastructure and our videoconference infrastructure. Video streaming is an important component of our current emphasis. Over three hundred campus courses have used course management systems (usually Blackboard) for partial delivery of course materials. The campus is currently developing a technology strategic plan in which distance learning figures prominently.

Through a contract with the Navy, Dr. Ken Lane and the National Center for Excellence in Distance Learning are developing MBA prerequisite courses, with development of an MBA scheduled in the next two years.

Our campus is experiencing a rapid shift to earnest distributed learning. Where previously we served occasional courses to a single remote satellite campus, we are now actively developing online courses, hybrid and videoconference courses that lead directly to a degree. The next two years will reveal whether the emerging internal and external partnerships will solidify or melt away amidst the turmoil of new ways of serving our regional academic needs. In this paper, I hope to illuminate many of the issues involved in such a rapid shift at our campus, and offer ideas on how our successes and failures may assist others.

"CNCplus telelearning" - A cooperative distant learning approach integrating University and Production with IT-technologies

Klaus Müller, Klaus Henning, Achim Streit

Centre for Learning and Knowledge Management and Department of Computer Science in Mechanical
Engineering (ZLW/IMA), University of Technology (RWTH Aachen), Germany,
KlausH.Mueller@de.bosch.com, henning@zlw-ima.rwth-aachen.de, streit@zlw-ima.rwth-aachen.de

Abstract: Co-operation between teams in different countries in research, construction and production as an important part of today's work should be a main component of university education. The project is based on a co-operation across the borders of three European Countries. The Project CNCplus telelearning is a sub-project of ELECTRA and aimed to promote collaboration between different groups of students from 3 European countries, and skilled operators of CNC production systems at distant working places. The collaboration is to be developed through approaches of experience-based learning.

Keywords: CNC, Information technologies, work organisation, production processes

1. Introduction

Current goals in educational research are the integration of telematic services in teaching and learning, focussing specifically on the impact and contribution of telematics for self-directed and collaborative learning. Co-operation between teams in different countries in research, construction and production as an important part of today's work should be a main component of university education. This challenge has been the reason for the ALMA-universities Aachen (Germany), Liège (Belgium) and Maastricht (The Netherlands) to start the project ELECTRA (Electronic Learning Environment for Continual Training and Research in ALMA). The project is based on a co-operation across the borders of three European Countries.

2. The CNCplus telelearning project

Presently the main task of a student of mechanical engineering or computer science is to learn the contents of well-defined subjects and to pass exams. The contents of the studies are defined by the faculties of the universities. Many other tasks relevant for the work in industry are not part of university education. Students of mechanical engineering have to master tasks in mechanical drawing, construction, calculation, material science and informatics etc. Missing tasks are group work, co-operative problem solving and getting a deeper understanding of socio-technical systems e.g. enterprises as a whole.

There are naturally differences between studying at Maastricht, Aachen and Liège. The main differences in the lectures are the numbers of students per lecture, the numbers of hours per subject and the contents of the subject even if they have the same name. Tasks comprising group work and problem-based learning are not part of the courses especially in Aachen and Liège. They are the way of teaching in the third and fourth year of studies in Maastricht. Direct contact with industrial production processes is rarely part of university studies.

On this background, the project CNCplus telelearning has been defined to take into account the demands on professional engineers in Europe today and tomorrow. Thus, the new course comprises the following tasks:

- Distant and co-operative working and learning via technological means
- Group work of peers as well as across peer groups (students and workers)
- Communication in English across European boundaries

- Understanding CNC-turning as a production process
- Learning to use the CAMplus software as an example of professional industrial control software.

The main objective of the project is to integrate experience-based learning in teams with the concept of distance learning. Students get exposed to the real production process beyond the computer simulation by linking simulation and production. They learn collaboration within and between groups at distant working places. The product to be made is a workpiece comprising three different components. The components are developed on a computer which is identical with a CNC system of a real manufacturing process.

Each of the three student groups works on one component of the final product, each group at another university. The three universities are located in Belgium, Germany, the Netherlands with three different languages spoken (French, German, Dutch). English is chosen as the co-operation language. It is a foreign language for all members of the project. The production site of this "enterprise" is a real production site, located at a fourth site in Germany.

The design and production can be simulated with the CAMplus system. A workplan of the CNC turning process is set up, simulated and controlled by each student working group in order to develop the best production process. The task of the production team on the production site is to collaborate with the student working groups in order to produce the workpiece according to the workplan. Skilled workers receive the CNC-production data and produce the components of the workpiece after some feedback and communication with the student teams . In CNCplus telelearning the individual students face three kinds of dialogues and means of co-operation:

- The dialog with the group members
- The dialog between the groups
- The dialog between the individual in a group and the system

The collaboration of the teams can be supported with different technical media. Within this CSCW (Computer Supported Co-operative Work) environment, communication between groups is supported by video-/audioconferencing, electronic mail, electronic whiteboard, file/datatransfer, shared window and telephone.

Thus, the CSCW environment enables the groups to work collaboratively on the internet. The student groups communicate mainly by email, audio or video conferencing. Construction and production data are sent through internet as well. The configurations change dynamically by the use of both real time and asynchronous communication. The different use of tools in the group and the requirements given by the production process play also an important role. The time synchronisation ofthe working processes in the four working places has to be dealt with. The interactive multimedia and telematic services integrate the industrial production in a collaborative learning process at universities.

According to the project aims and concept, test runs were made to record first experiences of students co-operating via these media. The first test run was made with groups who did not know each other before. They had different education and different knowledge. It caused misunderstandings and it led to limitations of the communication within and between the groups. A second and third test run showed better results in co-operation and communication about working processes in the groups. The students got to know each other and at the beginning of the test run they had more of a similar education than in the first test run. The main result was that similar background knowledge facilitates co-operation but it still does not help in communicating effectively in all phases of a co-operation process.

3. Conclusions

The test runs of this specific project have shown that the unique set-up of the project is a strong stimulus for engineering students to develop their intrinsic drive for international communication and co-operation. The different technologies and media used in parallel still cause substantial difficulties for the students as well as for the supporting technical staff. The computer networks still do not fit perfectly together across national borders and between the departments of different universities; the students reject the notion to learn in a cumbersome way to make efficient use of some of the technical means of transmitting drawings; the phone is still experienced as the easiest and most efficient means of communication. These difficulties need much more attention in developing new information technology and networks as is given to them today.

Considering Technology Use in Education: A Pre-service Education Course Model

Sharon Murray, Associate professor
St Thomas University
Fredericton, NB
E3B 5G3
Canada
Voice: 506-452-0473 Fax: 506-452-0611
email: murray@stthomasu.ca

Abstract:

A face-to-face and web-based course model is used to support a community of learners (pre-service teachers). This model seeks to create an environment that supports learners thinking about technology use in education rather than regurgitating an instructor's view. The students consider their readings and the perspectives of their classmates and create a digital portfolio that reflects their experiences and thought development. The course work also includes learning from experience and collaborating as a team to design instructional packages for K-12 educators.

Submission Category: Full Paper

The simulation program and chat in the e-Learning course in physics (mechanics)

Yasushi Nakajima

Abstract

To find the keys to make the effective e-Learning Introduction course in physics, this exploratory study were performed. E-Learning materials including a simulation program were made for the Introduction course in mechanics. The materials consist of 7 parts (vectors and their scalar product and mechanics, cross product of vectors and mechanics, differentiation of vectors and mechanics, Newton's laws and equations of motion, Taylor series and mechanics, computer simulation of circular motion, moving coordinate system and circular motion). In the course, there were two forms to participate. Students individually participated in one form, while they collaborated in the other form. In two forms, the interactions among contents, students and the instructor were observed. The observations suggested that the inter-relay chat and simulation program and easy questions that needs reflection of physical concepts are important.

Introduction

Although distance learning that utilize WWW (World Wide Web) and other telecommunication technology, e-Learning, have become popular in many countries, it is not established how to learn, instruct and collaborate in e-Learning, yet. Although there are some e-Learning schools, which prepare their students for entrance and qualifying examinations, in Japan, most of e-learning courses in the schools consist of electronic multiple-choice exercises and self-instructional text and don't have effective systems that help their students to obtain characteristic and difficult thought process in specific academic field. While it is established in the traditional classroom how to obtain characteristic thought process in special academic field, such as experiment and its report in the physics, it is not established in e-Leaning course. If methods to help students obtain thought patterns and process of various academic field in e-Learning course is developed, e-Learning course is able to be utilized as not assistant but principal and independent course and the methods seemed to result very large economical and educational profits.

This exploratory study attempted to find the key to help students to construct physical concepts in e-learning introduction course of mechanics. Electronic materials were made for Introduction course of mechanics. In the course, students read materials, did simulated-experiments using a given simulation program and submitted assignments and reports via the WWW. The course has two forms to participate. In one form (Individualistic form), students were individually able to submit questions to the instructor and were not forced to collaborate with other students. In the other form (Cooperative form), students were divided into groups, had to collaborate with other members in the same group to submit works. Relationships were discussed among the percentage of works, which students accomplished, instruction and collaboration in the two forms.

Course and the Learning Materials

This Introduction Course of mechanics was a part of preparation curriculum for the students to enter to School of Science and Technology of WASEDA University. The term of the course was 5 weeks in individualistic form and 3 weeks in cooperative form. This course was elective and the students that took the course weren't obliged to complete all works of the course. The Learning materials consist of the following 7 parts.

1) Vectors and their scalar product and mechanics
2) Cross product of vectors and mechanics
3) Differentiation of vectors and mechanics
4) Newton's laws and equations of motion
5) Taylor series and mechanics
6) Computer simulation of circular motion
7) Moving coordinate system and circular motion

Each part has works (assignments or reports) that students do and submit via the WWW.

Students

Students that took this course were 17-19 years. Although all of them have a lot of learning experience of mathematics, their learning experience of physics was variant. Some students took the 3 years advanced course in physics in high school; another student took only 1-year elementary science there. At the beginning of the course, an examination of basic physics (pre-test) was performed and students are divided to individualistic form and cooperative form, as distribution of the marks in the individualistic form is similar to that in the cooperative form. They lived in various parts in Japan and didn't know each other.

Individualistic Form

21 students individualistically participated in the course. The students read the content, did works, submitted works and questions using electronic mail (e-mail). Although the most of their questions were light, the instructors felt that a little of questions had included physical thinking. The results of the observation are the followings.

1) Students that submitted many questions completed many works using e-mail.

2) While only 1 student submitted physically important questions in 15 students that completed below 60 % of all works, 5 students did in 6 students that completed above 60% of all works.

Cooperative Form

19 students cooperatively participated in the course and were divided into 5 groups that consist of 3-4 students. The difference the average of the pre-test among 5 Groups is below 5 percent. In the group, students discussed in the inter-relay chat and electronic bulletin board system, understood the contents and made a work together. Each student was assigned a specific role such as 1) recording of discussion, 2) promoting to participate, 3) dividing a work into small parts and assigning the parts into all students 4) checking their work.

The results of observations are the followings.

1) One group (the best group) completed all works, while other four groups completed 43% of all works.
2) The best group was chatting about works and physical concepts during 11 hours, while the other groups were doing during 6 hours or less.
3) The number of submission in the bulletin board system in the best group is 147, while that in the other group is 74 or less.

Discussion

Important discussion is the followings.

1) In individualistic form, students that could complete many works seemed to think the essence of physics hard and submitted many questions. This suggests that the excellent individualistic e-Learning course in physics should have e-Learning contents that have many students to think the concept and essence in physics.
2) To have students understand moving coordinates, contents including simulation program of circular motion (the 6th part) were made. 5 students performed the simulations and probed the acceleration of the circular motion. The results of analysis of the simulations helped them to understand moving coordinates very much. This suggested suitable contents including computer simulation is effective in e-Learning of physics.
3) In cooperative form, the group whose students discussed each other using inter-relay chat during the longest time could complete all works. The chat records in the group indicate that students had gradually obtained correct physical concepts in the process of discussion without the instructor's advice. In this case the inter-relay chat was very effective to construct the students' physical concepts.

Conclusion

This exploratory study suggests the followings.

1) Utilization of simulation programs and inter-relay chat seems to be important for the effective e-Learning course in physics
2) Instead that teacher's real explanation on physical concepts with discussion in classroom, solving easy questions that needs reflection of physical concepts seems to be effective in e-Learning course in physics.

Systems

1) Server: Microsoft Windows 2000 Server, Microsoft Exchange 2000 Server, Microsoft SQL Server 2000
2) ELearning software: dotCampus (Interlect Co. Ltd.2-2-8 higashi, shibuya-ku, Tokyo 150-0011, JAPAN)

A Multimedia Storyboard Tool

Helmut M. Niegemann
Institute for Media and Communication Studies
Technische Universitaet Ilmenau, 98684 Ilmenau, Germany
helmut.niegemann@tu-ilmenau.de

Abstract: Up to now storyboards for multimedia learning environments consist mostly of copyed templates filled in by hand. The poster presents a software tool to generate storyboards using MS Powerpoint. Advantages of the tool are: ease of use, prototype-like presentation, inclusion of a data-base for the assets, revisability and recording of revisions.

A common way of communicating the design of an e-learning site to clients and programmers is through the use of storyboards. Although storyboards are used by people with (for the most part) a high level of computer literacy, there are almost no computer-based tools available. Typically, a design and development team decides for a photocopied template representing place for a sketch of the screen design and slots for information such as the name of the program, number of the screen, author, date, and directions for color, links, interaction, audio and video files to be integrated, etc. (e.g. Alessi & Trollip, 2001; p. 514 f.). These templates are normally filled in by hand.

The disadvantages of this procedure are obvious. Templates filled in by hand often require additional explanation for clients and other target groups, and cannot be easily presented to a group of people, e.g. using a beamer. Pictures, videos, and other assets cannot be integrated, and must be presented sepaately. Thus, there is an obvious demand for a computer-based tool for creating multimedia storyboards, similar to the well-proven tools for film scripts. Important criteria for the development of such a tool include:

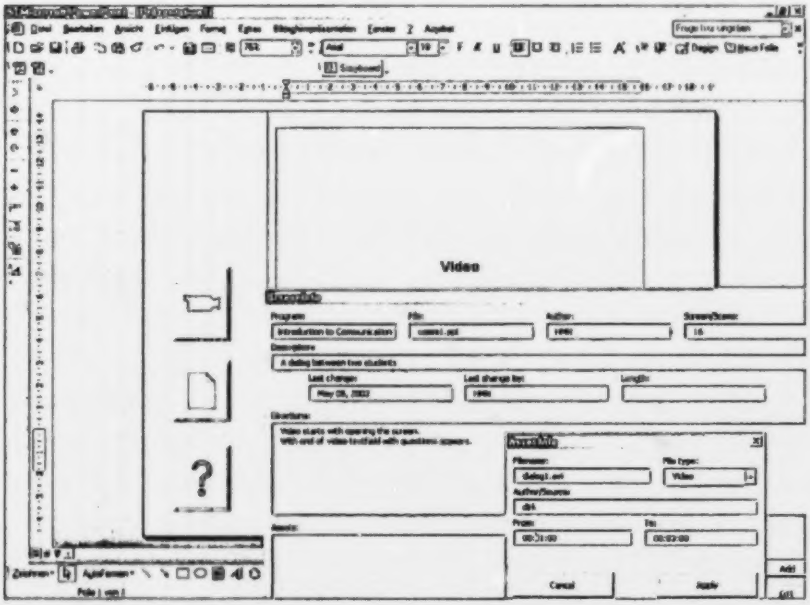

Figure 1: Mask to assess information

BEST COPY AVAILABLE

- ease of use
- possibility of presenting the storyboard both digitally and on paper (printout)
- prototype-like presentation
- inclusion of a database for the assets
- revisability
- recording of revisions (date, time)

Instead of programming new software, we discovered some of the features already realized in a common software product, Microsoft's PowerPoint. We therefore decided to use the features already available and supplement them by programming an add-in using VBA for PowerPoint. The main idea is to use the PowerPoint screens for sketching the web pages, and the notes fields to assess and represent all information and directions for the programmers.

To assess this information, we programmed a mask to be filled in for every slide (Figure 1). The content of these masks is automatically copied into the notes field. In this way, any printout of the slides with the notes fields represents one page of a storyboard, consisting of the screen on the upper half of the page and the necessary information below (Figure 2).

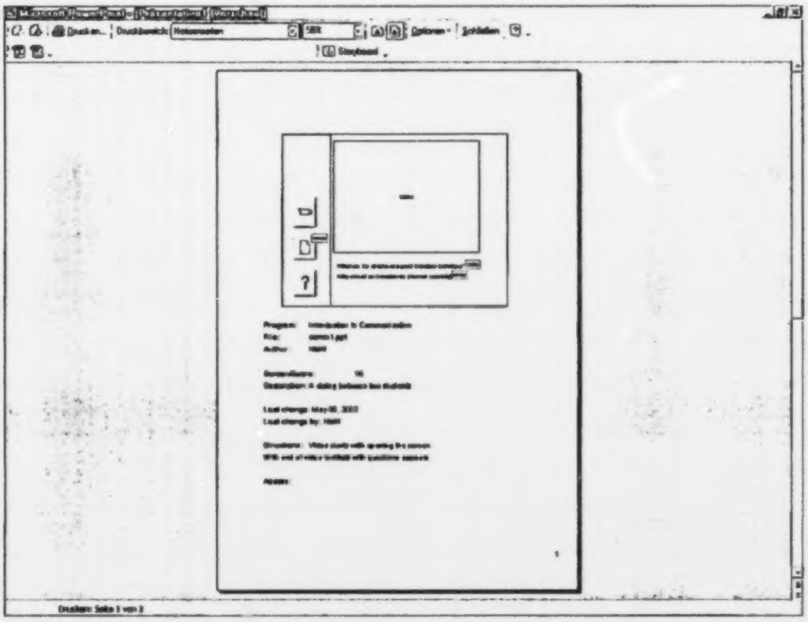

Figure 2: Printout of a page of the storyboard (A4 format)

Furthermore, we recommend the use of the yellow comment fields in the screen sketch. They are especially useful for conveying directions concerning the color of objects, branching information, etc.

The storyboard tool has been in use for several months now, in the context of two projects involving the development of multimedia learning environments for higher education in the fields of communication studies, electrical engineering, and medical informatics.

Emerging Perspectives on Learning, Teaching and Technology

By
Michael Orey

In this session I will demonstrate an evolving ebook that I created in collaboration with a group of doctoral students for use in a Masters level class on learning theories and instructional models. Since it is an ebook it, can be regularly updated, it can include interactivity and animations, it can be regularly added to, it can have contributors from around the field, and anyone can use it without charge for their classes. The obvious negative issue is what this would mean for book publishers?

In the Spring of 2001, I helped to create an ebook entitled "Emerging Perspectives on Teaching, Learning and Technology" with a group of doctoral students (http://itstudio.coe.uga.edu/ebook/). The purpose of this book was to provide masters students in the program with a text for a class that has the same name as the title of the book. The class is split between a survey of the most popular learning and cognitive theories (information processing, Piaget, Vygotsky, motivation, social constructivism, learning communities, and situated cognition) and a more in depth analysis of popular instructional models (cognitive apprenticeships, problem-based learning [including anchored instruction and webquests], constructionism [including project-based learning and learning-by-design], Six C's of Motivation, and conceptual change. In the past, I taught this class with a collection of papers and book chapters. I considered books such as Gredler (2001), Joyce, Weil, and Calhoun (2000) and Driscoll (2000), but none of these matched exactly with what I wanted to do in this class. I then proposed to a group of students the idea of creating a book for this class and I was able to get a group of eight doctoral students to volunteer. The creation of this book in the Spring of 2001 was just a beginning.

Unfortunately, because of a variety of factors, I was unable to teach the masters level class until the Spring of 2002 which I just finished at the time of the writing of this proposal. Part of the requirements in this class is to make a contribution to the book and I have given the students (34 of them) some latitude in defining what that contribution might be. One of the contributions has been to do some copy editing. Because we have not used a publisher, we have no resources for copy editing and so the burden is placed back on the students . Another contribution has been to create some sort of animation or interaction to help explain a complex construct in one of the theories in the book. Interactive animations that have been added now help explain Vygotsky's Zone of Proximal Development, Piaget's Equilibration, Assimilation and Accomodation, tracing a stimulus through the information processing system, how scaffolding works, and an animation explaining intersubjectivity.. Another task that some have taken on is to create a piece of web-based instruction that makes use of one of the models of instruction. One such effort was done to help children change their concept of history from one of memorizing facts to interpretation and sense making from various artifacts available to shed light on an historical event. Finally, some students elect to make a contribution to the book. This semester one student wrote a short chapter on the educational applications of behaviorism and another added Piaget's stage theory to that chapter. Every student must create either a high-level design document or a lesson plan that uses one of the instructional models. These examples are then placed into the ebook for later reference by future students.

Having run once through using this book for a semester, I have found that contributions were a little uneven. As a consequence, I plan on assigning teams to chapters who will then be responsible for a chapter. Chapter responsibility includes making sure that there are no spelling or grammar errors. Also, they must verify that all links are working and also generate any additional links that might be needed. Finally, they must examine the chapter for concepts that are particularly difficult or important to understand and design and develop interactive components to help others understand the concepts.

A number of years ago Broderbund started a series of CD-ROMs that were called, "Living Books." These books were designed for children and usually were based on an existing paper book such as Mercer Mayer's "Just Grandma and Me." Within these programs, children could click on various things that would react to being clicked with clever animations and sounds. The ebook described here is what I would also like to call a "Living Book," but in this case it is a living book in that as students use this book, they transform their book by contributing to it. In every other book that they have ever used in a class, at best they are transformed by it, with this book, the book and they can transform together. Further, I would like to invite all members of this academic community to use and participate in this book. In this way, the book is continually evolving as the thinking within the "community of practice" defined as our field evolves. There have been several e-journals to emerge in the past few years. I would like to see the emergence of this new kind of book with contributions being made by everyone whether it is animations, interactions, updates, edits, or creations of whole new chapters. I would also invite other members of the community to make comparable books covering other theories and perspectives in the field.

I make this recommendation while also thinking about a recent exchange on the ITFORUM listserv. I do not in anyway want to devalue the contributions that publishers in our area make to the field. I think they have an important role. If what I propose here is adopted far and wide, it would likely put some of these companies out of business. I try to balance the interest I have in supporting these publishers and the needs of my students who are asked to pay $60-$75 for any of the three books that I mentioned above (I just checked prices at Amazon on 5/6/02). I also balance that with the incredibly slow turn around for print-based publications. Finally, I want to consider the fact that the material that my students are reading is transforming them and they are transforming it. I would like to present the book in the form that it is in next fall and to discuss these issues in my session. There are an additional 40 students who will be using the book in the fall.

The book will shown at the conference on my notebook computer. I will have all the files on my machine, so that internet access will not be an issue. I may bring a projector to enlarge the computer screen. A plain wall or perhaps the availability of a screen would be required.

Building a Model of Collaborative Learning Environment

Abstract: This paper reports the development of a collaborative learning environment model, named RESOLVE, that contains the resolution of problems like learning methodology. Thus, making possible geographically away-scattered groups solve problems by using communication tools: chat, text editor and vote, provided by environment. Here are also presented the elements that give shape to the environment.

Introduction

The advent of the communication and information technologies has been building a track to certain changes in the educational system affecting especially the means of teaching and learning. Facing that, schools and universities that used to offer traditional schemes of long-distance education using cassette tapes and mail service, for example, had to reestablish it's educational broaches to include the Internet and it's communication and information technologies. As Ragoonaden and Bordeleau say, the students that learn by the Internet develop cognitive skills to the point of making themselves able to search, analyse, identify and summarize new information to conceive his/her own basis of knowledge (Ragoonaden & Bordeleau, 2000). Therefore, this paper stands to present a collaborative learning environment for a long-distance education, named RESOLVE, that has as apprentice methodology five stags of problems resolution. This environment was projected in a multi-agent architecture to support teachers and students in the teaching-learning process.

Computer Supported Collaborative Learning (CSCL)

The CSCL can be defined as an educational strategy in which two or more students build their knowledge through discussion, thinking over and decision taking, using the computer tools as mediators for the teaching-learning process (Ribeiro, 2000). The researchers of CSCL, for a long time, have been concerned about: interactivity, group size, joiness time and especially the learning methodology. Among the existent methodologies, the group problems resolution, is becoming the most popular in this environment, because learning occurring as a side effect expected is, interceded by the aquireness of new knowledge or by the improvement in performaning problems resolution (Rosatelli, 1999). The use of Artificial Intelligence techniques, mainly intelligence agent, is a new tendency to the CSCL development and, has been bringing good results like, for example, the MEMOLAB that is an experiment in which intelligent agents cooperate with students and teachers as co-pilots in the navigation through the Internet (Dillenbourg et al., 1996).

RESOLVE Collaborative Learning Environment

The RESOLVE collaborative learning environment goal is provide critic thinking development in a group of students, by using the five steps of the problem-based methodology. Here they are: a) reality observation: global view of the subject taken, identifying a problem to study; b) main-topics: identification of the main topics related to the problem; c) theory building: theoric explanation of each main-topic identified through the reading and researching; d) hypothesis elaboration: identification of possible hypothesis to solve the exposed problem(s); e) reality fitting: election and settlement of the most suitable solution. From this steps onwards was projected the RESOLVE environment architecture, as shown Figure 1.

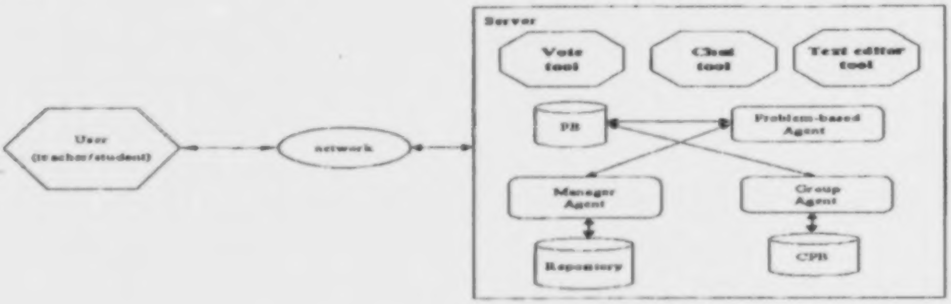

Figure 1 – RESOLVE Environment Architecture.

- Problem-based agent: restore and analyse the deposit's information to determine the group's ability to solve problems, thus, leads the groups to the direction of possible resolution(s). For that, this agent uses the problem base (PB) that has got the knowledge acquired by preview problem's resolutions;
- Group agent: supervises and shapes the group members' interactions, storing them into the collaborative profile base (CPB);
- Manager agent: run the environment's working as a whole managed;
- Repository: stores the documents which the groups produced;
- Chat tool: allow group members to discuss about certain topics in an informal way;
- Text editor tool: enable the group members to compose texts jointly;
- Vote tool: allow the members to decide about the away they may follow or even get to a common agreement.

The embodyness of the intelligent agents to the RESOLVE environment has as it's main goal assist teacher and students in the problem's resolution dealings and not replace the teachers themselves in the process of analysis and accompaniment of groups of students. The implement of this environment is being made with the help of the programming language JAVA 2.

Conclusions

In the proposed model of methodology, the teacher retires the centralizer role (the same one we have being having for years in standard classrooms) to assume the easiness maker, encourager and collaborator role. On the other hand, the student will participate more vigorously of the set up of his/her own knowledge, researching and collaborating to the solution of a certain problems. The usage of intelligent agents in the RESOLVE environment has a positive impact in the problem's resolution process, in the direction of providing and stimulating the mutual collaboration among the group members. The next step oh this work is use validation of the model proposed, in long-distance courses.

Management of the Educational Process

Ciro Martins, Paulo Ribeiro, Pedro Paraíso

{ciro.martins,pribeiro,pparaiso}@crb.ucp.pt

Abstract: The ability to teach and learn in a heterogeneous environment, subject to a fast renovation of contents and practices, leaves little room and time for the accessory. Nevertheless, and especially nowadays, we are aware that ephemeral and accessory elements are those, which increasingly provide strong appeals and calls. This constraint leads to a new and each time stronger concern about efficiency and effectiveness in the orientation and usage of the available formative resources.

Educare ... Educere

Without retaining ourselves in the socio-political implications of the concept of education, and if we just consider the phenomenology of the process itself, we are "compelled" to realize that we live in a time in which the definition of a new paradigm in education occurs, which in itself creates new constraints and opportunities. This scenario submits all actors of the educational process to a greater focus on the objectives and methodologies to use. Today, more than ever, it is a true priority that a correct balance is achieved between instruction and construction activities. On the other hand, and under the point of view of the pedagogical relationship, which is hereby established, the ability of knowing how to find a point of balance in the continuum between Authoritarism and Permisivity is a real critical factor.

A pedagogical system marked by authority-based relationships seeks to maximize the monolithic component of the instruction structure, leaving little autonomy, or even none at all, and little room for criticism, by valuing the ability to absorb, to conform to the norm and to obey. However, if authoritarism silences, permissivity isolates and empties, defrauding all expectations of the actors of the teaching/learning process. It allows no instruction, because it empties, it discourages all construction in that it isolates. Among other related phenomena, establishing the balance we mentioned above means, in Torrado's[1] words, to fight against a form of "an indisposition of 'modernity', which is characterized by individualism, primacy of the instrumental reason and loss of freedom".

In the society of knowledge and learning there is each time more room for the educational process to be placed within the angle of shared responsibilities. Shared by those who "teach" and by those who "learn", leaving both enough room for freedom and creativity.

Only in an adequate environment can the psychological mechanisms be created and stimulated, which are favourable to a fast adaptation and change, against the traditional resistance to the latter. The same environment encourages an ability to resist to the stress created by the constant lifewide and lifelong need to learn. To create spaces of freedom and responsibility for the process of Educare (to mould) and Educere (to give birth) to prevail and to affirm itself as the daily praxis of the universal citizen of the new millennium, is a challenge posed to all those who share responsibilities in this field.

It is a challenge posed to all methodologies and teaching/learning techniques but particularly to those, which, due to their intrinsic nature, are best suited at present times.

Methodologies and technologies of the new teaching paradigm

The creation and implementation of a new paradigm in teaching methodology is nowadays a high potential area, in which new practices and new relationships are defined and related to the traditional teaching and learning processes. The interest raised within the different teaching and training institutions for this new approach is promoting a fast expansion of teaching/learning techniques and methodologies. However, these methodologies cannot be seen as mere processes, in which flexible and expanded means for the divulgation and distribution of didactical contents is promoted. These new methodologies must be viewed as generator means of the dynamic relationship between the different intervenient parties of the educational process – institutions, tutors and learners. They will allow the reformulation of the present processes of teaching, learning and interacting.

The tutor's role acquires therefore a new relevance, in that it faces a whole set of new and important challenges. Tutorship is a teaching support methodology, which despite being suitable from the most classical to the most modern teaching models, is particularly assertive within the constructivist approach. Thus the tutor should have a profile and a set of competences, among which we find the need to explore and take the best advantage of the new teaching technologies at his/her disposal. The new roles and skills a tutor is required to have should be understood and defined within a specific context, according to the technical and pedagogical restrictions of the learning environment, the characteristics of the target public and the pedagogical model in effect.

If, on the one hand, in a perspective of face-to-face or classroom teaching the tutor gets a reduced feedback from the participating elements, in an ICT supported learning situation, on the other hand, the direct relationship between learners and tutor facilitates the fast and efficient perception of the problems and concerns of the former. However, in a classical situation, the tutor can obtain verbal or non-verbal feedback, which is sometimes impossible in a teaching typology connected to the new paradigm. In this area, the asynchronous interaction "tools", which are normally used as support ad complement to the learning activities, do not provide an effective support to the resolution of this kind of interaction needs. Here, the synchronous interaction "tools" assume a particular relevance, covering the gaps left by the former.

Applying the approach

HEINET (Human Education Interactive NETwork) is therefore an essential "tool" for the implementation of this kind of methodological approaches within the new teaching paradigm. By including technologies, which as a whole allow a synchronous interaction, it enables all intervenient elements in the educational process to communicate in real time: the participants interact together and simultaneously, thus stressing one of its basic assumptions – the equity in the educational process. By operating in a synchronous environment, the tutor can add a nearer and more immediate presence to the educational process, which beyond the intrinsic motivational character also allows a more effective socialization of the tutor-learner relationship.

Another aspect of particular importance in new teaching methodologies is the system's capacity to allow the tutor a fast and effective evaluation of the teaching process. If in a classical presence-based methodology the tutor has at his/her disposal a set of pointers, which allow him/her to actively evaluate the level of progression of the educational session, in an approach where technologies allow the real distancing of the participants, such pointers are often disregarded or inexistent. Therefore, the use of such "tools" is essential, where beyond interactivity, eventually spoken or written, a "visual interactivity" is also provided, in such a way that it allows both intervenient parties to identify and acquire the different educational perspectives. However, these synchronous communication tools are as more relevant and acceptable, as greater the flexibility they provide to those who make use of them.

The correct use of information and communication technologies as a support to the new teaching paradigm encourages the training processes to develop with great independence towards space and time. To communicate and to evaluate simultaneously, without temporal or spatial restrictions – to be there, without actually being there. The "BeThere" tool we use is a further example of this kind of methodology, where we aim at applying the new teaching paradigm, strengthening the philosophy of flexible learning.

Designing for a moving target: design and development of content for delivery in a wireless environment

Beverly L. Pasian
Bodec Corporation
Canada
bpasian@bodec.com

In the fall, 2001, a content development team (including project management, instructional designers (IDs), subject-matter experts (SMEs), and technologists) was formed with representatives from McGraw-Hill Ryerson (MHR), Seneca College and the Northern Alberta Institute of Technology (NAIT). The challenge for this group was to develop content that could be accessed on a PDA in a wireless environment and, potentially, enhance student success in a first-year college accounting course at the 2 partner colleges. They had 10 months to meet this challenge as the project consortium prepared for the delivery of the mlearning pilot project in September '02.

This presentation will describe the unique experiences of this group, including challenges they encountered and the strategies they used to overcome them, as they collaborated to explore the potential of mobile technology and develop compelling 'mcontent'.

Developing the mcontent

Agreeing to an instructional design model for this project was not difficult: it was decided to adopt an outcome-oriented, learner-centric approach currently in use by both colleges. The real challenge lay in deciding how to create enriching content for a device never before used by the SMEs or IDs.

Several issues affected our design and development efforts. Some of these included:

- Constantly changing PDA devices meant that the potential of the technology was largely unknown and enormously difficult to design for. Early on a critical question emerged: what criteria would we use to determine what could make *effective* mcontent?
- Faculty and instructional designers were largely unfamiliar with the device, so time and resources had to be allocated for training and orientation. Jumping from the technological learning curve to the creation of compelling content for that device was a challenge.
- Uncertainties surrounding the type(s) of content that may or may not work on the market-ready PDAs influenced the choices available to the SMEs. Involvement of our IT colleagues was critical and influential.
- While the demand for learner and faculty support was unchanged, it became apparent that the complexities of the support resources could increase dramatically.
- And, of course, for many pilot exercises, unforeseen costs and resource-demands emerged. Unlike in an elearning environment, however, where experience could allow us to anticipate what these costs might be, mlearning design, development and production requirements were more difficult to anticipate. Flexibility on the part of all project partners was the order of the day.

What were the results of our efforts?

Based on initial assessments of and orientation to the PDA—along with our reliance on our 'elearning experiences—an initial wish list of content objects was made. Among the many items included on the list were: Learner and faculty manuals, Online learner support, Audio and video clips, Access to accounting software, more Excel templates, Dynamic financial statements, Access to 3rd party Web sites, Practice quizzes, Games, contests, eBook, Online assessments, Generic/daily news questions, Animation of some textbook problems, Course calendar, and collaborative learning opportunities.

Once testing occurred, however, many of these content types were removed from further consideration and would not be included in the September '02 Pilot. The methods used to make these decisions, along with some qualitative feedback, will be shared in greater detail in the presentation.

Conclusions / observations

This project is still in its implementation phase (the Pilot will be running until December '02), making firm conclusions inappropriate at this early stage. It is reasonable to note, however, at least 2 key observations from the initial design stages of the content development effort.

Partnerships between academe, content providers (eg, publishers) and technology suppliers are becoming increasingly important, as technology delivery options become more complex or "bleeding edge." When a radically new technology is being introduced that could have such a drastic effect on the learners' success, the involvement of various partners to the team is critical. There needs to be an ongoing, open and frank dialogue that is devoted to exploring the potential and limitations of the technology and how it will affect the accessibility of content and the learning and teaching experiences. As always, the bottom line (or question) has to be: can this content delivered via this technology enhance student success?

The role of the academic technology support centers is becoming critical. There are new offices emerging in higher education where instructional design and technology specialists work: the difference is that in this new environment, the awareness and appreciation of each other's role has never been greater. Instructional design, content development and production has, at least in this project, benefited enormously from the participation of professionals who are bilingual—they can speak the languages of instructional design and technology, fully aware of the impact each will have on the learning experience.

eInstruction: A Gateway to Effective eLearn

The whole world is being kept on changing in very short span due to the uninterrupted resource are made available from the world of new vision, technology. Education is not an exception. Educational Technology and Instructional Technology has revolutionised the classroom pedagogy. The uses of modern amenities within the classroom environment are easily accepted by the teachers and learners but media and multimedia is still away and their use is being observed restricted in the classroom pedagogy. This is one of the barriers and one should think of why the teachers or the people employing their efforts are not able to get their endeavours visible in the classroom environment. The prime concern of this paper will be the 'Instruction' and eLearn. It will be discussed in the light of Educational Technology and Instructional Technology. Following will be the key area of eLearning.

1. Instructional Design for eLearn. -eInstruction
2. Learning environment in Learning and eLearning. eLearn Environment.
3. Classroom Pedagogy. -ePedagogy
4. Developing Software (Course Content) - Need of Pedagogical Approach. -eCourse Content.
5. Integrating Conventional Teaching-Learning Process and eLearn. eTeaching-Learning.

The world of education cannot be replaced by the another system, one is to think of introducing the modern trends to the system to enable it to accept the change as such changes are being observed in the habits of the common people. It is called the life, the technology is the part of the life and one cannot separate it but one can make it more accurate or inaccurate. The question is: Do we really find the ET or IT in the lives of teachers teaching in the educational institutes? This answer can be wisely put forward disguised but the fact is very different. The reason is the chasm between the people who are teaching (not only teachers, all those who are backbone of the teaching community) and the people who are engaged in developing any kind of software (Video, audio, multimedia, etc.). To look into the world of education and technology needs a very different eye, a balanced eye that can look into the problems faced by both communities. As learning can be eLearn, why Instruction can not be eInstruction.

The teachers, the policymakers, the teacher educators, educational Researchers have to deviate from the conventional strategy to emerging scenario of the world of teaching and learning. eLearn is introduced at the level of technocrats, not edu-technocrates, for that we need an extra force to make all our endeavours be real not superfluous.

In the paper all the points will be discussed in the terms of developing course content to enhance eInstruction for better eLearning. The fundamentals will be derived from the Educational Technology, Instructional Technology, Educational Psychology, Pedagogy, IT, Role of Media in effective curricula transaction, use of Media technology, Developing Multimedia Software, Asynchronous and synchronous modes of Instruction, etc.

Blended WBI: A Meteorology Mixture

Any mixture requires consideration of the appropriate mix of ingredients. With blended WBI, it is more than a question of how much face-to-face vs. web components. It is also a question of the characteristics of the web components. The prototype web-facilitated Meteorology I course at Embry Riddle Aeronautical University might be thought of as a "double blended" course. Not only does it blend web components with face-to-face instruction, but it also blends various types of web components. The results from this study are informative as to the ingredients and the proper mixture of those ingredients to enhance learning and reduce costs.

Project Description

The Online Course Development Project at Embry Riddle Aeronautical University was designed to document and study the development and implementation of several different types of web based instruction. The prototypes ranged from highly engaging, totally web-based content to simply posting supplementary lecture materials on the web. The web-facilitated weather course used a mid range development model that utilized the web for guiding student use of existing content and participation in learning activities created specifically for the course. The web components were utilized to reduce class meetings. Students attended lectures on Tuesdays, but completed web activities in lieu of attendance on Thursdays.

Web Components

The web facilitation approach blended four inherent web capabilities into the course.

1. The web can be used to present information that introduces and focuses attention on key concepts in existing content such as the textbook and CD-ROM for the course.
2. The web provides a rich resource of information that can be incorporated through appropriate web research learning activities.
3. The web provides communication tools for collaborative learning activities.
4. Web pages can be programmed to respond to learner input.

For the web-facilitated weather course, those capabilities resulted in ten components for each week of the course. The introduction for each week contained an introduction to the content for the week, a list of required activities for the week, a list of outcomes for the week, and foundational information such as key terms, formulas, and tables. The components for each week also included an introduction to the textbook reading assignments, a web research activity, a collaboration activity, and a CD-ROM activity. The summary for each week presented diagrams and illustrations as interactive manipulatives that focused on key concepts. A self-assessment of randomly generated multiple-choice questions with feedback was also available for repeated attempts each week.

Face-to-Face Components

For the web facilitated weather course, students met in a face-to-face lecture setting on Tuesdays and were encouraged to attend tutorial sessions on Thursdays. Since lecture time was decreased by half, the instructor used the web to help her identity the topics to focus on during the lecture. Students were required to post topics they wanted addressed during the Tuesday lectures by noon on Fridays. The instructor used that input to determine not only the topics, but the level of importance for each topic to adapt the focus of the lectures.

Results

An end of course survey obtained data on student demographics, perceptions of the value and usefulness of the web components, and satisfaction with the blended approach. In general about two-thirds of the students indicated a positive response to questions related to satisfaction with the course and its effectiveness. They found most of the web components to be useful and appreciated the variety of learning opportunities. They appreciated the flexibility of completing activities at their convenience. Grades for the course were comparable to those in traditional courses. However, there was some negative feedback suggesting some students preferred the traditional class structure over self-directed activity.

The usage data from the survey indicated the most high ly used and helpful components included the activities list, introduction to the reading assignment, web research activity, collaboration activity, and summaries. It should be noted that the web research and collaboration activities were graded, which likely was a contributing factor that they were highly used and valued. While the introduction and the CD ROM activity were rated as highly used, they were not rated as highly helpful. It is conjectured that the introduction was used more than valued because it was the first screen of weekly activities, and that the CD ROM was used more than valued because it contained engaging content of a supplementary nature. The online self-tests were rated as only moderately helpful with a corresponding lack of use. That perception may have been because graded unit tests were short answer rather than multiple-choice questions. The foundations and outcomes components were perceived as not helpful and were not used.

These results confirm that students value and use components that help them know what to do, focus on important content, or are graded assignments. The results also imply that engaging activities are likely to be used, but there also needs to be instructional value if they are to be perceived as helpful as indicated by a comparison of the summary and CD ROM activities. Both activities engaged students through interaction with the computer, but the content in the summaries was more directly related to the core content of the course, and therefore, perceived as more valuable. From a development perspective, creating the foundation and outcome components may have been wasted effort since they were not valued or used by students. However, from an instructional design perspective, it was critical to define outcomes to insure alignment between expectations, instructional elements, and assessment, and little extra effort was required to post them as a web component.

For the best return on resource investment, development should be targeted toward helping students focus on the important content for the course and guiding their activities. Development of those types of components requires relatively little content development and only low-end development skills. However, design that communicates directions and expectations clearly is essential and must be completed carefully. From this study, it is recommended that user testing be incorporated into the design process early and frequently to identify and correct misconceptions.

While this study indicates that creating web pages with programmed interactions engages the students and are highly valued if they provide appropriate instruction, resources for creating those components are relatively costly. In this prototype, the animated diagrams and programmed interactions were representations of information in the book and were created using Flash. While the content design was minimal, the Flash design and development was resource intensive. Because of their perceived value, such components should be included, but incorporated judiciously due to the resource cost required.

From the instructor's perspective, the blended course required more preparation time to adapt lectures and monitor student participation. It also required more communication with students outside of class time since they had increased electronic access. The return on those investments was more student participation and interest in the course content.

Implications

The results from this study indicate that blended courses that use a variety of web components to reduce class-meeting times have the potential to enhance learning while reducing costs.

The variety of web activities in the course provided a range of learning opportunities to better meet individual student needs. The collaboration activities provided learning opportunities for those who learn best with social interaction. The web research and textbook reading activities provided opportunities for individual learning. The interactive maniuplatives provided 'hands on" exploration. Adding a variety of web activities to the traditional classroom lecture provided additional avenues for individual students to interact with content in ways meaningful to them. While there was not a significant improvement in performance by the participants in this study, there was a high level of satisfaction with the variety and flexibility of learning activities. None the less, there were a few students who indicated they preferred the passive lecture environment to self-directed participation.

Web facilitated courses offer resource utilization efficiencies by reducing development costs and optimizing classroom facilities. The development time to contact time ratio for the web facilitated weather course was approximately 30 development hours for each instructional contact hour as compared to 100 - 400 to 1 for totally online course content. By utilizing existing content such as the textbook and maintaining some face-to-face contact, development time is reduced significantly. Face-to-face time also reduced the electronic communication time experienced in many totally online courses. Using the blended approach also cut classroom usage by half which represents a huge savings potential for capital and maintenance costs.

While this study indicates that blended courses may represent a significant potential for enhancing learning while containing costs, a note of caution should be sounded. Feedback from some students indicates that the transition to blended courses may encounter resistance. The negative feedback seemed to stem from engrained expectations that teaching means instructors lecture while students listen. Implementing blended instruction will require a student mindset shift that they need to become actively involved in their own learning.

Summary

This study indicates that blended courses have potential for enhancing learning and reducing costs. Further study needs to be done to determine the best use of web components in a course and the best way to blend them with face-to-face instruction. Student expectations will also need to be addressed, but it seems likely that blended courses can be used to reduce class meetings while maintaining learning effectiveness.

Digital and Educational Empowerment in Urban Teacher Education Environments

Joyce Pittman, Ph.D.
Teachers College of Education
University of Cincinnati
USA
joyce.pittman@uc.edu

Abstract: This paper describes research findings from the transition of two teacher education courses, a distance learning and instructional technology course in transition from a traditional learning environment to an e-learning web-based system in teacher education. There is an enduring and growing interest and investment in digital and Internet technologies as the new model for education reform for the 21st century. This shift has forced attention on complex issues that have emerged as education moves swiftly into the world of cyber learning and teaching. Perhaps the most pressing and complex issues in public education are those of digital equity and empowerment of people of color and other traditionally underserved populations in urban and rural communities through the use of new educational, digital, and Internet technologies (Pittman, 1999; 2000). Findings from the study provide profound implications for infusing technology into teacher education programs in urban universities.

Introduction

Aspects of the digital divide addressed in this paper include two broad goals. The major goal is to provide information on strategies helping online communities emerge in urban communities. Strategies to connect the principle of digital equity to the empowerment of people and humanism in e-learning environments will be demonstrated. The examples will communicate the idea of cultural sensitivity, new literacies, computers, telecommunications, and digital technology as valid tools to increase people performance, change the nature of living, learning and teaching.

Virtual Learning and Technology

Technology can exacerbate the problems in the world or redefine achievement by providing technology and Internet access to information to all people to communicate effectively in a global world. This session describes a digital learning portal designed to connect home, school, community and teacher education field-based experiences. Digital empowerment includes ideas, systems, and practices that build and restore confidence in all people and their ability to think, to want, to know, and to produce in the technological arena along with the mainstream population (Freire, 1997).

Social, Economic, and Digital Education Crisis

Education in America is facing a social, educational, and digital technology crisis in urban schools that serve large traditionally, underserved populations, and especially African Americans. We need to openly examine the portable characteristics of virtual professional development, learning, and teaching models in urban and mainstream environments at local levels. What does the concept of "empowerment" mean for online teaching and learning in traditionally underserved teacher education programs that outreach to schools in urban communities?

Defining Empowerment

In an attempt to further refine the definition of empowerment in this paper, we will attempt to do so by analyzing two models that best represent suitable access to computers and the Internet. Therefore, the cases featured in this poster presentation will move beyond projects and the idea of simply making the technology available to in schools. The criteria will include essential information that encourages participants to consider access and outcomes in a variety of ways.

Abstract: This paper proposes a method for color indexing and similarity image retrieval with single and multi color region, that employs 2D+ String for represent spatial relationships. This method consists of 2 steps: database construction and image retrieval. In database construction process, the color regions of each image in database are extracted. An image is represented by a set of color regions, corresponding to minimum bounding rectangle (MBR). These features are used for creating index for each image in database. In the image retrieval process, a target region with size, color and spatial relationship of each region are specified via a user interface tool. This allows very fast indexing of image collection by color contents of image. Furthermore, information about the identified region, such as color, size and location, enables a rich variety of queries that specify both color content and spatial relations of region.

Introduction

In the past few years, there has been a growth of media-rich digital data such as images, video and audio. This trend has motivated research in rich effective store and retrieve of large image database. The best known image database system is IBM's query by image content (QBIC) (Faloutsos, et al. 1993, Flickner, et al 1995), which allows an operator to specify various properties as image content of a desired image. This method specifies a query by drawing rectangles with the desired colors, shapes and sizes. Moreover, users do not need to paint the entire color layout of the query, the unpainted area will be treated as "don't care". The locations, size, shape and color features of rectangles are used in computing the similarity measure, but the spatial relationships among rectangles are not used. This paper proposes a scheme for image indexing and retrieval system by using color spatial relationship. The scheme enables a rich variety of queries that users can specify both color content and spatial relations of region. The 2D+ String (Bowon, et al 199) technique is employed for representing spatial relationships among each color region.

The Proposed Scheme

The proposed scheme consists of two main steps namely: color region extraction and comparison of image similarity.

1. Color Region Extraction

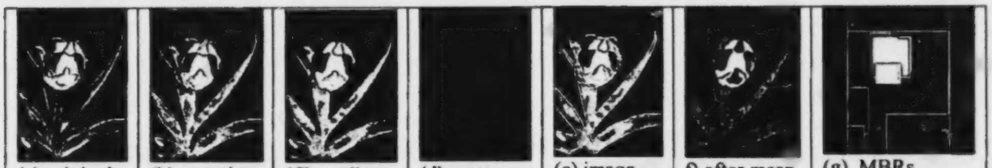
In this process, RGB color space of each image is transformed into HSV color space. The image is then transformed into the image representation by using the perceptual color model. Next, the HSV is quantized into color space with 18 hues, 2 saturations and 2 brightness values. The process quantizes color into 76 colors. Images may be corrupted with noise during quantization process, so noise is removed by using a color median filter. Then, color index for each region of an image is calculated by using Eq. 1, then image are transformed to 76 gray levels with color index component for image labeling process.

$$\text{Color Index} = \{\, i \mid ((\min(|H_i - H_j|, 180 - |H_i - H_j|) + |S_1 - S_j| + |V_i - V_j|))\,\} \qquad (1)$$

Then each image is scaled into the size of 200 x 200 pixels. as shown in Figure1. Finally HSV value, color index and MBR coordinate of each region in each image are stored in database.

2. Comparison of Image Similarity.

This process is used to compare the similarity between the query and images in the database. The comparison is depended on the given query that can be divided into cases: query with single region and query with multiple regions.



(a) original (b) quantize 76 (C) median filter (d) gray scale 76 (e) image labeling f) after mean color) (g) MBRs

Figure 1. Color extraction.

a) Query with Single Region.

The similarity measure is defined as the similarity between color index of segmented image and the query image, that overlap together as describe at Eq. 2.

$$\text{Area}_i = \{r_i \in R \mid R = R_i \cap R_q\} \qquad (2)$$

Where Area_i is a color region I of image in image database that have the same color index and area with query area. R_q is a query region. R_i is a image region in image database.

Images that satisfied the condition are retrieved. Then the rank of similarity is arranged. Many parameters are used for the purpose namely: color dissimilarity distance (CDD), Location Dissimilarity Distance (LDD), Size Dissimilarity Distance (SDD), and Area Dissimilarity Distance (ADD).

b) Query with Multiple Regions.

The calculations are the same as that of single region but the location of all regions are used to compare the similarity by using 2D+String (Bowon, et al 199). Then the images are ranked by using Eq. 3.

$$MD_i = W_c CDD_{i,q} + W_s SDD_{i,q} + W_A ADD_{i,q} \qquad (3)$$

Experimental results

The scheme is tested with a database that contains 2001 pictures, which stored in JPEG format with size 250x170 or 170x250. First, properties of each region in the image are extracted. The color index, color value, area and MBR coordinates of each color region are stored in the image database. Then users can draw rectangles with desired colors to specify a query picture on left-lower frame. After query comparison completes, the rank of each image is displayed on the other interface in ascending order. For single region retrieval process, query images are created various size, position and color 50 experiments. The values of CDD, ADD, LDD and SDD are set to 60, 90, 90 and 80, respectively. The weight of color (W_c), area (W_A), location(W_l) and size(W_s) are set to 40, 30, 10 and 20, respectively. The average of precisions with in 50 queries is 0.97 and average of time for have relevant image is about 1.7 seconds. Another experiment, that don't have relevant image used average time for retrieve about 1.687 seconds. Recall was not calculated because the database is large and it is difficult to estimate the total number of image in one category, even approximately. Multi regions retrieval process, the values of CDD, ADD and SDD are set to 60, 90 and 80 respectively. The average of precisions with is 0.91 and average of time for retrieval is about 16.63 seconds form 30 queries on a personal computer with AMD thunderbird CPU and 128 MB RAM.

Text-to-Speech in Learning Thai Language for Foreigners

Wichian Premchaiswadi*, Nucharee Premchaiswadi**, Wadida Chawangwongsanugul*,

Abstract: Text-to-Speech synthesis can be coupled with computer aided learning system and provide a helpful tool to learn a new language. The conversation dialogs are one of the important materials for practical used of each language. In the past, the learner could learn the correct pronunciation from tapes that come with the books. However, the learners could learn to pronounce only in the limited words in the book. When they find new words that do not have in the book, they must guess what is the correct one. In case of Thai language, the pronunciation of each word becomes more difficult because the Thai language is a tone language. This means that pitches are meaningful. A word pronounced with different pitches carry different meanings. This paper presents the work in progress on Thai text-to-speech for helping foreigners in learning Thai language. The aim is to build a system that could generate sound from the input Thai sentences.

Introduction

It is hard to learn a new language without adequate support. Now a day, computer becomes cheaper and more powerful. Therefore, it is used in many applications including language teaching. Text-to-Speech synthesis can be coupled with computer aided learning system and provide a helpful tool to learn a new language. The conversation dialogs are one of the important materials for practical used of each language. In the past, the learner could learn the correct pronunciation from tapes that come with the books. However, the learners could learn to pronounce only in the limited words in the book. When they find new words that do not have in the book, they must guess what is the correct one.

In case of Thai language, the pronunciation of each word becomes more difficult because the Thai language is a tone language. This means that pitches are meaningful. A word pronounced with different pitches carry different meanings. There is no spacing between words and no special mark to identify the end of a sentence. The Thai vowel forms do not follow initial consonants; some are placed before the initial consonants, some after the consonants, some above the consonants, and some underneath the consonants. The vowels that are "complex" forms (i.e. composed of more than one part) can be placed around the consonants.

There are 5 distinctive tones (pitches) in Standard Thai. They are

1. mid level tone (here represented with the number 1)
   for example: *khaa1* (to be lodged in)
2. low level tone (represented with the number 2)
   for example: *khaa2* (Galanga, an aromatic root)
3. falling tone (represented with the number 3)
   for example: *khaa3* (I, slave, servant)
4. high level tone (represented with the number 4)
   for example: *khaa4* (to sell)
5. rising tone (represented with the number 5)
   for example: *khaa5* (leg) .

From the example mentioned above, it can be seen that it is very hard to the foreigners to pronounce a Thai word correctly.

The proposed system

This paper presents the work in progress on Thai text-to-speech for helping foreigners in learning Thai language. The aim is to build a system that could generate sound from the input Thai sentences. The synthesis system receives input Thai text and separates it into token according to the grammar of Thai language (Pantumetha, 1998, Dutoit, 1997). The sound of each word is generated.

Experimental Results

At this point of time, the system can generate sound from the variety of user input and shows how to produce sound for each word as shown in Fig. 1. However, some words are still not correctly produced and need to improve in the future.

Abstract. CyberTutor is an interactive web-based program that functions as a personal tutor for the student, offering help with the problems when requested or in response to incorrect answers. CyberTutor collects extensive feedback which is processed to inform the teacher about current performance and lack of foundational skills of each student, to identify troublesome problems and concepts for the class, and to inform the problem author about flaws in the problems. CyberTutor contains problems involving Newtonian Mechanics at the freshman college level and at high school AP level, many of which involve conceptual issues as well as quantitative ones.

Introduction

CyberTutor is a platform for delivering homework and illustrative problems via the web, combined with tutorial features that help students work problems through to a correct solution. Like a human tutor might, CyberTutor presents each student with a problem, provides hints or simpler subproblems at the student's request, assesses the student's responses immediately, and gives feedback if the student's answer has particular recognizable deficiencies. CyberTutor strives to equal the range of question types used by a human tutor, and its repertoire includes several free response answer types: symbolic expression, fill in the blank, and mouse-drawn curves. This allows us to de-emphasize multiple choice and which often encourage students to guess, and numerical answer types, which provide the teacher with little basis for determining what the students did wrong.

The CyberTutor problem library includes 500 problems involving Newtonian Mechanics and Electricity and Magnetism at the freshman college level and 100 at high school AP level, many of which involve conceptual issues as well as quantitative ones. CyberTutor has been used by over 1000 students in versions of introductory Newtonian Mechanics at MIT and in several high-school AP physics classes over the past three years. Pre- and post-testing conducted by Prof. Ogilvie in 2000 (Ogilvie, 2000) and by Prof. Pritchard and Dr. Sofia Morote in 2001 (Pritchatd & Morote, 2002a) showed that CyberTutor use correlates over five times more strongly then written homework or class attendance with reduction in the number of errors made on the MIT final exam elative to an MIT final unsuccessfully taken in the preceding term. Moreover, CyberTutor use correlated twice as strongly as written homework with gains on a standard test of conceptual knowledge administered before and after the course. Written surveys indicate that students felt they learned more from using CyberTutor than from graded written homework. In addition, the ratio of students recommending its use next year to those not recommending it has risen to consistently each semester, and it is now 7 to 1 (yes: no) ratio.

Feedback for the Teacher

CyberTutor is a tutor that also works for the teacher. In addition to maintaining a standard gradebook, CyberTutor collects and analyzes detailed data on student performance. For each part of each problem displays statistics on numbers of right and wrong answers, hints and solutions requested, and median time. This information enables the teacher to see where the students are having trouble and what that trouble is in time to correct it during the next lecture. Wrong answers can be displayed in decreasing order of frequency given, and specific responses recorded for future students who give these answers. In this manner, CyberTutor can respond to over 50% of the wrong answers submitted.

Skill Profile

We have recently shown that CyberTutor can assess students with two orders of magnitude less error than a three-hour final examination (Pritchard & Morote, 2002b). This huge improvement arises from a combination of the longer time students use CyberTutor over the term (3 hours a week versus the 3 hour-final) and an almost order of magnitude reduction of error for a given interaction time that is achieved by inclusion of time and wrong answers per problem data in the assessment algorithm. We are now working to calculate and display a comprehensive current assessment of each student's skill level. Using all available information submitted by each student for every CyberTutor problem attempted, we shall update each student's current skill rating on each of 100 topics in the syllabus, about 25 percent of which are foundational skills. CyberTutor's assessment algorithms should enable the assessment of each topic at the same reliability level as the overall grade on a well-designed three-hour examination. This assessment will be called a skill profile.

In addition to providing detailed information about the progress of the class and the students, the skill profile has two impacts. The growing number of college students in introductory courses who have serious deficiencies in foundational skills is a serious problem - perhaps due to the educational diversity of today's freshmen. The skill profile will allow the identification and remediation of such deficiencies before the student becomes discouraged and "drops out." It has another revolutionary implication: if used for the homework grade, it would reward the student for learning instead of penalizing him/her for wrong answers. This can change his basic strategy from avoiding lost points to learning the most per unit time.

Because we hope that CyberTutor will eventually be used by thousands of students, it is worth the effort to make and improve a library of excellent problems. We have a group led by experienced teacher-tutors who propose, select, write, and review problems. The detailed data collected by CyberTutor allows the author(s) to improve the educational effectiveness of each homework problem. The author (or teacher) can make specific comments to students who give specific wrong answers. The time spent on each problem and subpart, which hints and subparts were needed to enable students to proceed to the solution, the number of wrong answers preceding the correct response, and the students' opinion of the effectiveness of the problem provide a guide for improving individual problems and problem parts. Confusing questions (questions that elicit consistent wrong answers or comments), overly time-consuming problems, and problems that the students judge educationally ineffective can be improved or eliminated. The hint structure can be extended so that students rarely run out of hints and subparts. We are working toward determining the educational efficiency of each problem, allowing optimization of the homework in order to provide more learning per unit time.

Education Research

CyberTutor is a powerful tool for education research (see our latest findings at URL: http://torrseal.mit.edu/effedtech.) Its built-in statistical capabilities allow every teacher to analyze the data for his/her own class easily and quickly – something that, in the past, was logistically impossible. Such data give immediate feedback that allows the teacher to redirect a portion of the next class to correct misperceptions, add a particular insight, etc. while the topic is still being studied.

Technology Driven Course Redesign in the Humanities

Poster Session

Florida Gulf Coast University was founded in 1997. Since it's inception FGCU has been a pioneer in developing and applying distance learning principles and practices. In 2000 FGCU Instructional Technology staff and faculty from the Division of Humanities and Arts began the year-long application process in seeking a grant from The Pew Grant Program in Course Redesign sponsored by the Center for Academic Transformation at Rensselaer Polytechnic Institute.

The grant program required a challenging three round application process. Over almost a year 10 higher education institutions were selected as grant recipients out of over 400 applicants. Each institution was awarded $200,000 to redesign a course with national significance with an eye toward improving student learning, solving an inherent problem in current course delivery, and reducing course costs. Understanding Visual and Performing Arts (HUM 2510) was the course selected for revision by the FGCU redesign team. The poster session will present the results of this redesigned course and demonstrate the instructional innovations that have been incorporated in the current Understanding Visual and Performing Arts course.

Course Drift: The Problem

Because of the nature of humanities courses, they are often taught in large lecture sections or in small classes that emphasize face-to-face interaction. Faculty in the humanities have been reluctant to incorporate technology into these courses because of their perception that technology might eliminate active engagement with issues and activities that are central to humanities courses. As a result of growing enrollments and the lack of belief in the efficacy of technology based learning FGCU has been forced to add multiple sections while hiring a growing number of adjuncts to teach HUM 2510. At FGCU the number of Understanding the Visual and Performing Arts sections has grown from 7 sections with 180 students in 1997-98 to 30 sections with 800 students in the 2001-2002 academic year.

Like other undergraduate institutions and community colleges, we face two critical problems in providing our required humanities to our students: we do not have the necessary resources to offer increasing sections of the course and we have experience course drift because of the large numbers of adjuncts that we have employed to teach the same course.

Course Redesign: A Technology Based Solution

The solution to our problem at FGCU involved a redesign of HUM 2510 with these goals in mind:

1. Improved course quality by controlling course drift
2. Improve student learning
3. Improve course cost per student ratio; i.e., decrease cost
4. Introduce a scalable staffing model
5. Utilize technology to achieve new course goals

We are in the midst of the course redesign process for HUM 2510. The entire project spans five semesters and is proceeding as seen below:

- Summer 2001: Team building and Assignment of Redesign Tasks
- Fall 2001: Development of Infrastructure and Course Materials
- Spring 2002: Pilot Redesigned Course
- Summer 2002: Refine and Finalize Redesigned Course
- Fall 2002: Full Implementation of Redesigned Course

The key to this project has been the integration of instructional technology in the course redesign. Projected outcomes of the course redesign project highlight improved student learning, course stability, and a cost savings of $331,000 over the next five years.

Why is The Project Significant?

Technological innovation is one of the key aspects of the course redesign project. Of particular importance is the use of technology to enhance student interaction, rehearse writing skills, and learn content via practice examinations. These tools have permitted a realignment of teaching strategies and supervision. Students *are* engage in a student-centered learning experience that is accessible on and off campus and is available when they are best ready to learn. The application of WebCT as a course management tool permits large numbers of students to access consistent course content while being engaged in small group discussions as well as individual and collaborative writing assignments.

Perhaps the most important element of the course redesign that has been the writing intensive nature of the learning. Key to this process has been the introduction of an online essay grading technology known as the Intelligent Essay Assessor (IEA) from Knowledge Analysis Technologies. The IEA is a unique program that grades essay questions according to the meaning of terms and phrases as opposed to just the presence of key words or phrases. The content meaning relationships of student essays are compared to the content meaning relationships of course materials through a program that creates "semantic space" for the course. The strength of this program is that the scoring ability of the computer program approaches that of human scorers. This permits a significant offloading of work from instructors to a computer without sacrificing quality. In a practical sense it saves instructors from having to read and grade up to 2400 essays per year for the course. This saves significant time, frees personnel resources, and introduces scoring consistency across course sections.

Testing the IEA is a key component of the redesign project. If the IEA proves successful it opens tremendous opportunities to redesign other courses that require writing intensive learning. Application of this tool is not limited to the humanities.

What Will Attendees See

This Poster Session will provide an updated presentation on the Pew Grant Program in Course Redesign project at Florida Gulf Coast University. Included in the presentation will be results of project cost savings, student learning, and results of the IEA testing. The course staffing model will be presented along with the impact of the project on instructional programs at FGCU.

One of the requirements of the Pew Grant Program in Course Redesign is that institutions receiving grants actively share what we have learned. Conference attendees will be some of the first to see the HUM 2510 redesign project results. In addition, attendees will be able to view the final version of the Understanding the Visual and Performing Arts course via a short multimedia presentation. A limited number of CD's containing the project presentation will be available for interested viewers.

USING WEBQUEST IN PROJECT-BASED LEARNING

Jorge Joel Reyes-Méndez, Health Care Department, Universidad Autónoma Metropolitana Xochimilco, México,
joelr@cueyatl.uam.mx

Abstract: Many institutions are moving towards project-based learning as a solution to producing graduates who are creative, can think critically and analytically, and are able to solve problems. We focus on using WebQuest model as an innovative teaching and learning strategy in a project-based learning environment by giving the students a framework to train them in this skill set. The purpose was to access the students' skills in framing and solving problems using the Internet. They worked in groups and each group had to pick a topic for their project, develop, design and present it in a Web format. Students were very positive toward the project, enjoyed teamwork, able to think critically and became active participants in their learning process. WebQuest can be used as an innovative and effective tool for the acquisition of problem-solving skills.

Introduction

The Metropolitan Autonomuos University campus Xochimilco was born with the Modular System, wich involve project-based learning as a solution to producing graduates who are creative and can think critically, analytically, and solve problems. Since knowledge is no longer an end but a means to creating better problem solvers and encourage lifelong learning, project-based learning is becoming increasingly popular in educational institutions as a tool to address the inadequacies of traditional teaching. Since these traditional approaches "do not encourage students to question what they have learnt or to associate with previously acquired knowledge" (Teo & Wong 2000), project-based learning is seen as an innovative measure to encourage students to *learn how to learn* via *real-life* problems (Boud & Feletti 1999).

Project-based learning

Whether you call it problem-based learning, project-based learning, engaged learning or constructivist learning, our students will only come to thrive in this new information landscape if we engage them frequently in challenges calling for fresh thought. The focus is moving from content towards problems to provide a more realistic approach to learning and to create an educational methodology which "emphasises real world challenges, higher order thinking skills, multi-disciplinary learning, independent learning, teamwork and communication skills" via a problem-based learning environment (Tan 2000). However, this model can be further strengthened with the inclusion of Internet into this project-based learning environment to enhance the students' learning experience.

We extended this contention further by using Bernie Dodge's model, WebQuest to create a Web-oriented project. By doing so, we hope to further develop the students' ability to become creative and critical thinkers and analysers, as well as problem-solvers, within this Web-mediated environment. This learning mode is constructivist in approach whereby the students participate actively in their own learning process and construct their own knowledge (Jonassen et al. 1999).

The WebQuest Model

WebQuests allow students to complete authentic projects and use technology to find and present information and, at the same time, alleviate some of the barriers teachers may find in their attempt to work in the confines of project-based learning. In planning for such learning, we should always start with the end in mind. A WebQuest can provide the educator with the project for a unit of study. After reading through a specific WebQuest, the teacher can then begin to select the standards to be mastered. An alternative way to start would be to select the standards, and then find a WebQuest that would help master those standards. Subsequently, the teacher can decide which enabling activities need to be taught. Every WebQuest has an Introduction, a Task, Resources, a Process, Evaluation (with a Rubric), and a Conclusion.

As students locate expert level technical information to bring to bear on the problems they are investigating during intense, authentic study, they frequently end up with a tremendous amount of information and little if any way to construct meaning from that information. In order to make good use of the wealth of information available on the Internet and truly enable students and non-expert teachers to engage in in-depth, authentic inquiry, WebQuest should provide frameworks for analyzing and using complex data sets. Such explanatory features will help demystify information and consequently increase its utility for non-experts.

Some of these tools will scale data to help eliminate variables that create noise but not relevant information. In other cases, examples of expert applications of information will provide enough context to assist novice users in making their own interpretations. These tools will help students select meaningful data sets for interpretation and evaluation, explore and identify significant parameters and variables, and perform analytical operations on subsets of data.

Environments for WebQuest will help develop and distribute unique models, simulations, and tools that will augment understanding and enable sophisticated analyses and solutions. In addition to providing information, the WWW is unique as an educative medium that allows the communication and publishing of new knowledge to both selected and broad audiences. The WWW is at once a place to gather information and a place to publish one's findings, thus allowing users to contribute to the learning community's growing resource base. WebQuest should include technologies for direct and moderated communications and publishing for additional sharing of resources and development of a science learning community. Students enjoy WebQuests because they are given the opportunity to use the Internet to find and apply information.

Conclusion

This paper presents and discusses the use of WebQuest in a project-based learning environment to equip students with high-order thinking and problem-solving skills and to enable them to experience an IT-oriented learning situation. From the results, we are able to conclude that by integrating Internet into the teaching and learning process, the conventional project-based curriculum model is reinforced and strengthened. The Web project in this course enabled the students to exercise their creative and critical thinking skills in solving their design and development problems, work collaboratively to gain team-based experience, and to face the real-life situation of problem-solving. This is a student-centered learning approach which allows them to construct their own knowledge and understanding, and determine their own learning goals. The role of the teacher, on the other hand, changes from the *sage on the stage* to a *guide on the side*, assisting the students in the construction of their knowledge.

As such, the use of Web project are an innovative and effective teaching and learning strategy because they motivate the students in their learning process and help them to acquire good problem-solving skills. As evidenced by this project, students became very active participants in their learning process instead being passive learners, and were able to use various digital media elements to accomplish their project. These findings are significant in that: by using a Web project, we can move towards the constructivist learning mode, which is student-centric. In this context, the students had to utilise their prior knowledge in other disciplines to breakdown the problem into component parts, and then synthesize and re-construct a possible solution. This experience is invaluable in creating a new generation of effective problem-solvers for the current professional needs. We successfully integrated Internet into the classroom, instilling effective *learning how to learn* and lifelong learning attitudes into the students, and they are in line with the Tapscott's (1998) proposition that today's generation is IT-savvy and look to digital media for learning and they expect universities to provide IT-oriented programmes in their curriculum as well as in teaching and learning methodologies. As such, Web-oriented model serves as a strong framework for teaching and learning in this respect. WebQuest like many other learning solutions, can be appropriately used as an innovative and effective tool in a project-based learning environment for the acquisition of problem-solving skills.

Issues in the development of online teacher education

George Gadanidis, Sharon Rich
Faculty of Education, University of Western Ontario, Canada
ggadanid@uwo.ca, srich@uwo.ca

Abstract: This paper discusses issues related to the implementation of an online content and discussion component to replace large group lectures in a pre-service teacher education setting. A large number of post-secondary institutions and school districts are considering how to create or expand online teacher education programs (and education programs in general) – and there seems to be a hurry to put *something* online. Our experience and research in this area should offer some guidance for other institutions interested in online teacher education.

Task forces involving leaders from government, business, and education (Ontario Ministry of Education/Ontario Ministry of Training, Colleges and Universities, 2000, June; Web-based Education Commission, 2000) envision a comprehensive e-learning enterprise with full courses being delivered online. In this context, we consider issues in the development of online teacher education based on our experiences in replacing large group lectures with online modules and discussion.

Prior to 2001-2002, elementary pre-servive teachers at our Faculty of Education received 18 hours of small group instruction (25-30 students per class) and 9 hours of large group lectures (200 to over 400 students per lecture) in the areas of mathematics and language arts. In 2001-2002, in an effort to improve pre-service teacher learning in the areas of language arts and mathematics, we replaced the 9 large group lectures with 9 online content modules and online discussion conferences. The goal was to move from the simple transmission of information through face-to-face lectures toward online interaction through online modules that offer content, links to web-based resources, video, and web-based interactive activities, as well as online discussion conferences. This new and innovative direction for pre-service teacher education builds on existing expertise and capacity in our Faculty of Education to offer online courses through its Continuing Teacher Education program.

Our shift from large group lectures to online content and discussion is an attempt to better align the pedagogical content we teach with our teaching processes. The online component allows for students to interact with ideas represented through various media, including web-based simulations, and supports the online sharing and discussing of ideas and issues. We strongly value the *process* of coming to know as we see knowledge as something that students build from the inside out rather than something that is passed on to them ready-made. Our teaching philosophy is of heightened importance in a faculty of education setting, as it both process and content in the courses we teach. We are sensitive to situations where we may use learning processes that are not aligned with the pedagogical directions we promote for our students. For example, when giving large group lectures, we sense contradictions between promoting a learning environment where students actively participate and collaborate and delivering this message in a lecture hall with 200-450 students.

In the proposal stage of the project, we experienced both resistance and support. Concerns were raised about student access. How do we know that the over 400 students affected will have access to the Internet? If they all depend on our computer labs for access won't this make access impractical? Concerns were also raised about notification of program change to students. Application forms were processed and acceptance letters were sent out to students prior to the proposal for this project. Should prospective students have been told ahead of time that part of their program was online? Support came in the form of a recent external review of the Faculty of Education that suggested consideration of incorporating online technology into the pre-service through the instructional methods developed and used successfully in the Continuing Teacher Education. Also, with increasing enrollment over the last 3 years, physical space in the Faculty is at a premium. For example, in 2000-2001, the mathematics lectures were scheduled at 8 am on Monday morning, which increased both tardiness and absenteeism. Support for the initiative also came from the mathematics and language arts instructors, who felt that the lecture format did not provide optimal effectiveness. The shift from large group lectures to online content and discussion tried to better align the pedagogical content with the teaching processes. The online component allows for students to interact with ideas represented through various media, allows interaction with web-based simulations, and supports the online sharing and discussing of ideas and issues in each of the 9 modules. After discussion of the issues, it was agreed that the initiative should proceed for the 2001-2002 year as a pilot project that would be assessed through surveys of the pre-service teachers and instructors.

Interestingly, when students were asked at the general orientation presentation in September 2001 whether they had regular access to the Internet outside of the Faculty of Education, over 90% indicated with a show of hands that they did. Only approximately 50% of the students answered positively when a similar question was asked at the September 2000 orientation. The anticipated problem with access did not appear to be an issue for students in their online participation in 2001-2002. Though the general format of online content and discussion conferences was used in both language arts and mathematics, there were differences in implementation. For example, in language arts, each workshop instructor was responsible for monitoring, facilitating and assessing student performance in the online component of the course. In contrast, in mathematics only one instructor was responsible for the online component. Workshop instructors indicated that compared to the large lecture format of previous years they have noticed a significant improvement in terms of pre-service teachers' completion of readings prior to attending the workshops. Instructors also saw a benefit in reading pre-service teachers' ideas and issues online and incorporating these in workshop activities and discussions. Issues of workload arose, as there were obvious differences in workload between presenting a lecture and facilitating and assessing online participation and discussion.

What made the implementation of the proposal possible in a short time (proposed in the spring 2001 and implemented in the fall of 2001) was the existing capacity to offer online content and discussion in our Continuing Teacher Education program. What is unique about the course delivery experiences in the Continuing Teacher Education program of the Faculty of Education is that rather than simply accepting technology as a given, members of the distance education team with pedagogical experience have worked with the web designer and other technology staff to develop and integrated system that places the needs of learners and instructors first. Early recognition that the technology needed to be almost invisible to the end user meant that all team members had to think about and learn how to write content for the web and facilitate assessment practices appropriate to the learner and the medium. The program of online delivery of instruction developed by the Continuing Teacher Education program of the Faculty of Education includes a process to facilitate the effective management of students and course conferences and a set of course management tools that enable efficient registration, records administration and student evaluation. In 2001-2002, these processes and tools were adapted and used in the language arts and mathematics component of pre-service teacher education. First drafts of online content for each of the modules were authored by team leaders in language arts and mathematics in the spring and summer of 2001. The pre-service teacher candidates were informed of the new direction of their program through a letter sent to them in the summer of 2001. The online technology was demonstrated to students at a general orientation presentation in September 2001. The online component will be part of the elementary mathematics and language arts teacher education programs in 2002-2003.

Creating an Effective Training Model: One Size Does Not Fit All

Finding an effective faculty training model for online and web-enhanced courses has been an on-going challenge in the Center for Teaching and Learning at Wright State University. On one hand, there is the question of how to best train the faculty to effectively use the course management system for the university, WebCT. The other major consideration is how to help faculty make the transition from teaching in a traditional classroom to a virtual one. Finding a model to meet both needs has been an evolving process, but one that I believe has been as instructional for the trainers as it has been for the trainees.

We began using WebCT two years ago, and the initial training sessions followed the company's suggested two-day fare, which, we quickly discovered, turned out to be very unpopular and quite ineffective. True, after two full days of training the faculty had a good fundamental understanding of the tools in WebCT, but the benefits of this type of training were short lived. If the faculty did not continue to use WebCT immediately after the training, and many did not, then what they learned was quickly lost. When the faculty did find time to work in WebCT, they were quickly overwhelmed and consequently frustrated. To compound the problem even further, the version of WebCT we were using at the time, 2.x, was not user friendly. There were too many clicks to achieve any results, and the path leading to the right combination of clicks was not very intuitive. Some changes definitely had to occur.

The next logical step was to tailor the training to fit Wright State's own particular needs. We cut the two day session down to a one day fundamentals training, with two hour supplemental training sessions held at later times. The hope was that the faculty could be introduced to WebCT's functionality, but when the training began to fade then the two-hour sessions would provide the needed refreshers. These sessions were focused on specific aspects of WebCT, such as course management or quizzing, so that faculty could choose whichever sessions they needed to brush up on. Another need we realized was to allow faculty time to work with their own materials in a workshop atmosphere. We setup developmental sessions where faculty brought their own materials on with them to the sessions (typically they were stored on a shared drive that they could access from the training lab) and they were able to get more productive time. So instead of spending two hours in a session and then going back to their offices to apply what they learned, faculty brought their own materials and not only received training but got real work done as well. The sessions were limited to a few participants and the method worked out extremely well.

To complement our WebCT training sessions, we created an online course that every faculty member was enrolled in. The course contained step-by-step instructions on many WebCT tools and functions as well as instructions on typical course management issues (requesting courses, adding students, resetting courses, etc.). The third area in the course housed materials for instructional design and course planning.

Basic concepts of instructional design had always been part of our course management system training; it simply made it easier to approach the majority of faculty about their teaching and learning practices in the context of discussing the applicable tools in WebCT. However, there was also a need for a more detailed and more formalized approach to designing courses for online delivery. To accomplish this, faculty would meet individually with the CTL's instructional designer to start the course design and planning process. After the initial design processes for the course are completed and an outline is produced, the next steps in the process are to establish a work schedule with the faculty member and to get the other members of the Distance Learning/Multimedia team involved. Of course the faculty member will be responsible for providing the learning content, but depending on the learning activities and the learner profiles the presentation of the material will change. Our goal is to assist the faculty member as best we can so that her technical sophistication, while enhanced, is not crucial in delivering the course. The faculty member is seen as the content expert and we support him or her as best we can.

This model worked well for a limited amount of faculty. Some faculty went through the entire design process and completed their courses in a 15 to 20 week time period. In addition, they also completed training in WebCT so that they could use the course management system. For many, this entailed around fifteen hours of training in WebCT and endless hours of development time in creating the course materials. The results for these faculty members were outstanding. Their courses were well thought out and well designed for an online learning environment. In addition, the faculty members had some confidence in using the course management system and so were able to progress independently, just as they would in a traditional classroom.

However, last year the Provost announced that there would be an online section of every general education offering at the university. Suddenly our existing training model was being stretched dangerously thin; we needed a training component that would ensure quality course design as well as a clear understanding of WebCT but at the same time not deplete our limited staff and resources. So, the idea was to develop a five week, mixed mode training course that would combine the two main initiatives: quality course design and detailed technology training. We wanted the participants to finish the five weeks with an online course well underway, including a completed design layout and several weeks of materials ready to go. We also wanted them to have a thorough knowledge of WebCT.

In summary, our training model in The Center for Teaching and Learning at Wright State University continues to evolve as we try to remain flexible enough to effectively meet the faculty needs. The five week training seminar was developed to fit an emerging need, but of course it's not for everyone. There is a tremendous time commitment, and for those faculty interested in web enhancing their courses it is generally viewed as too much. So we continue to offer the other trainings and services as well, hopefully meeting the needs of all our constituents.

Using Knowledge Levels with AHA! for Discovering Interesting Relationships

debra@win.tue.nl

Abstract: In this paper we show how the AHA! system was (modified and) used to create an adaptive course in which the course material is presented in three levels of difficulty. The aim of the experiment is to perform data mining in order to find good candidates for meaningful relations between reading times, difficulty levels and test results. We want to discover information between all the stored evaluation data and show a selection to the teacher so that he can carry out appropriated modifications in order to improve the course.

Introduction

In the past years, we have seen an exponential growth in the use of web-based technology in distance learning systems. At the same time, more and more artificial intelligence techniques have been applied to these systems to improve students' learning, named as Intelligent Tutoring Systems. The union of web-based learning with Intelligent Tutors has given place to the current Web-based Hypermedia Adaptive Systems that allow adapting the teaching to each individual student through Internet. But the methodology used for its construction is static. Once the construction of a course is concluded and it is published in the Web for its use, the system starts logging information about the users' interaction with the course. However, teachers only use this information for student evaluation. We propose a dynamic construction methodology that uses the system usage information to discover some information that will allow the teacher to improve the course. We will use association rule mining to obtain useful information that helps the teacher to modify the course in order to improve student performance, thus making it educationally more effective (Zaïene, 2001). In order to prove our methodology we have developed some web-based hypermedia adaptive courses using the AHA! system (De Bra & Calvi, 1998). We have chosen AHA! because it is a simple general-purpose hypermedia adaptive system, it has a high degree of adaptation and it's available in source code. We have modified AHA! in order to make it use different knowledge levels. In this way the AHA! engine can adapt the content and navigation of the course to the specific knowledge level of each student. Another advantage of AHA! is that it automatically stores usage information in logs files. We converted these files to a database in order to do association rule mining.

AHA! with knowledge levels

AHA! is a general architecture for building adaptive hypermedia applications. We have modified it in order to be able to control the adaptation depending on the student's knowledge level. To do it, we have modified: the user model, the domain model and the adaptation engine, see [Figure 1].

- Domain Model. One course consists of several chapters with several concepts, but the concepts and the questions related with these concepts are divided in three levels of difficulty (high, medium or low).
- User Model. The student's knowledge for each concept, initial test or final test can be only one of these values: 0 (not yet read), 10 (low), 50 (medium) and 100 (high).
- Adaptation engine. Before studying a new chapter the students have to do an initial adaptive test to discover their initial knowledge level. The system then presents them only the concepts with this level. Each concept has an activity to evaluate the student's knowledge about this specific concept. When the students have visited all the concepts they have to do a final (multiple-choice) test to evaluate the their knowledge about the chapter at this level. If they obtain a medium or high level in the final test they can go to a higher level. If they are in the highest level already they can go to the next chapter. In each chapter everything starts again: initial test, studying pages and doing activities and then the final test.

Discovering association rules and Conclusions

We are using a genetic algorithm to obtain association rules (Romero et al., 2002) from the user evaluation data. The association rules relate variable values. Genetic algorithms are a paradigm based on the Darwin evolution process, where each individual codifies a solution and evolves to a better individual by means of genetic operators (mutation and crossover). In general the main motivation for using genetic algorithms for rule discovery is that they perform a global search and cope better with attribute interaction than greedy rule algorithms often used in data mining. The format of the rules we want to discover is:

```
IF Variable1 = Value1 (AND Variable2 = Value2 …) THEN VariableX =ValueX
```

Where:

- Variable1, Variable2, VariableX are the database's field names (times, levels and scores).
- Value1, Value2, ValueX are the values of the corresponding database fields.

We want to discover relations between knowledge levels, times and scores that help the teacher modify the course's original structure (joining concepts, changing concepts from level or chapter, etc.) and content (eliminating or improving bad questions, bad pages, etc.). We have developed a course on Linux with the modified AHA! and we are now obtaining usage information about different types of students with different initial knowledge about Linux. We expect to have enough usage information in a few months to apply association rule mining and see how useful the discovered relations are. We have tested our genetic algorithms with the data obtained from the evaluation of a Web-based Hypermedia Course on the subject of Rheumatology (Romero et al., 2002) and we showed that they can produce potentially useful results. We are also developing a more sophisticated evolutionary algorithm to obtain more comprehensible and interesting rules.

Essential Elements: Prepare, Design & Teach Your Online Course

Raymond M. Rose, Concord Consortium, United States of America, ray@concord.org

Alese Smith, United States of America, alese@concord.org

Abstract. Essential Elements is the latest publication written by staff at one of the Internationally renown eLearning organizations. It builds on over six years of work in online education and from our experience helping to develop hundreds of online courses. We show you how to create and teach a successful online course. There are just seventeen "basic, indispensable, necessary" parts that make up a successful high-quality online course. Include them all in yours and you are nearly guaranteed success.

Essential Elements is the latest publication written by staff at one of the Internationally renown eLearning organizations. It builds on over six years of work in online education. Chris Dede, from Harvard University says about EE; "Its model will aid instructors in reconceptualizing their teaching to take full advantage of the new interactive media." And Zahrl Schoeney, from Curry School, University of Virginia proclaims; This book gives you the closest thing to a surefire formula for creating successful online courses..."

This book, with our *Essential Elements* gleaned from our experience helping to develop hundreds of online courses, reveals just what that difference is. We show you how to create and teach a successful online course.

There are just seventeen "basic, indispensable, necessary" parts that make up a successful high-quality online course. Include them all in yours and you are nearly guaranteed success. Is that all there is to it? Yes, it is that simple. Of course, making sense of and implementing the seventeen *Essential Elements* may take some work—but that is what this book is all about.

We describe these *Essential Elements*, and show you how to implement them in a truly high-quality learning environment for your students. With tips addressing everything from technology to student assessments, from community building online to collaborative teaming, and from pacing issues to the "chunking" of course activities and materials, we have the virtual classroom covered. In addition, we illustrate the tips with practical examples from our experiences.

To fully explain our method for creating successful online courses, we have developed The Concord Consortium e-Learning Model. The following nine key characteristics define The Concord Consortium's approach to delivering quality e-Learning.

1. **Asynchronous collaboration.** Participants don't have to be logged on to the course simultaneously; they work in an asynchronous environment in which text-based, threaded discussion and collaborative problem solving form the core learning strategy.
2. **Explicit schedules.** Instructors of online courses that rely on collaborative discussions schedule lessons within a specific timeframe so participants can share similar experiences and insights.

3. **Expert facilitation.** Online courses are led by a qualified person specifically trained in online facilitation.

4. **Inquiry pedagogy.** Designers create effective online courses -- with many specific elements that contribute to sound pedagogy for inquiry learning.

5. **Community building.** Course designers and instructors are proactive in designing and nurturing a community culture in which participants are supportive, honest, and willing to take intellectual risks.

6. **Limited enrollment.** There are between 12 and 25 participants in a class to keep collaborative learning manageable.

7. **High-quality materials.** Course designers include the widest feasible range of media and activities to appeal to different styles of learning.

8. **Purposeful virtual spaces.** Online, course designers create explicit structures so the community gets what it needs without interrupting the flow of content-based discussions. Typically included are a "Student Lounge," a "Questions about Assignments," a "Technical Questions," and a "Class Meeting" discussion space for debriefing course experiences.

9. **Ongoing assessment.** Online assessment is a continuous, ongoing process. Instructors find evidence of achievement in participants' daily contributions to online discussions. They learn each student's unique voice and approach to solving problems through their postings.

The type of online course that we will help you develop is one in which you will have clearly written assignments that engage your students in active learning with each other, and in which you, as the instructor, play an integral role as a facilitator of that learning. You will use the Internet both as a resource and as a means for connecting yourself and your students based on your mutual interest in the content—regardless of your individual schedules, geographic location, or physical ability to come to class. You'll choose a courseware package (such as Blackboard, Lotus LearningSpace, WebCT, to name just a few) to display the course assignments and reference materials as text, with graphics, colors, and multimedia to enhance the presentation, along with a discussion area that allows for student-to-student and student-to-instructor interaction.

The type of online course we hope to help you create is one in which you and your students will communicate and collaborate on a regular basis. Within the course, students will assess their own growth and learning through group discussion and reflection, peer review, instructor feedback, and self-evaluation. The richness of these interactions will translate into positive and meaningful learning experiences for your students that will carry over into their face-to-face lives.

Online Education for Adults: An Andragogic Approach

Ryan, Mark
National University
USA
mryan@nu.edu

Serdyukov, Peter
National University
USA
pserdyuk@nu.edu

Abstract: Online education may have to undergo curricular and methodological transformations to best serve the growing population of working adult learners. It would seem that a fundamental understanding of adult learning theory in an online environment is imperative in order to adequately meet the needs of this distinct population.

Andragogy is a specific learner centered theory geared toward teaching adults. As a methodological approach, andragogy understands that the adult learner has had different life experiences as compared to a pre-adult - and so adult teaching and learning methods are geared to the "different" kind of student (Knowles, 1991). This may have profound implications on the instruction and scholarship of the working adult learners (WAL), especially in online education.

The goals and curriculum of an online course from an accredited university should, undoubtedly, be the same as of the onsite, campus-based one. Nevertheless, the difference between a higher education course given online as opposed to one taking place in a classroom, is in the unique methodological approach. Accordingly, there is a need to articulate a particular educational philosophy (i.e. andragogy - learner-centered adult education) when developing an online course, training an online professor or orienting an online student. An appropriate philosophy informs a coherent methodological approach so that a course will be designed to supply the appropriate curriculum, a professor will be prepared for distinctive techniques, and the WAL will be assured that he or she will receive the most enriched learning experience in an online format. Therefore, an important relationship exists between adult learning and online education based on the andragogical notion that adults are self-directed learners.

Here are six assumptions about the adult learner. The WAL:

- is likely to be self-directed;
- has a life experience that can serve as a unique learning resource;
- is usually a goal-oriented learner, not a curriculum oriented learner;
- is more likely to initiate and sustain learning due to genuine motivation rather than external incentive;
- demands an explicit initial framework of study, and then the freedom to pursue knowledge within those borders;
- hates to waste time.

Following andragogical tenets in implementing online education for the adult student, it should display a distinct power sharing collaborative course design. Correspondingly, facilitators and learners become participants in an educational process that is both active and reflective. The key responsibility for leadership in the creation and maintenance of an online course clearly rests with the trained instructor. Ultimately the curricular and methodological success of an online course is revealed by the educator's rapport with his or her adult students. Online instructors need to be both competent and caring facilitators aware of cognitive psychology (how we learn affects what we learn) as well as the affective psychology involved in making a student feel welcomed, supported, and able to achieve.

Collaboration is *modus vivendi* of online education. Collaborative learning is based on the andragogical assumption that adults are self-directed learners who are shaped by the accumulation of authentic personal experience. Moreover, their desire to learn grows out of a need to confront an ever-changing reality. Given their goal-oriented approach to learning and an ever more crowded personal calendar (adults hate to waste time!), a self-paced asynchronous design has proven to be a most effective instructional online approach.

Thus, the logical extension of these assumptions for an online class is a collaborative asynchronous learning format. Such a learner-centered format calls for both direction and support. The key factors in providing a foundation for a partnership among facilitators and learners is to provide both direction and support for all. It is usually up to the facilitator to determine direction (i.e. how to carry out the learning process) and support (the learner's competence to take part in that process) although students familiar with this paradigm can also partake in a shared decision making process. Support for the online adult learner is provided through a learning environment that meets both the adults' cognitive and affective needs. An academic atmosphere in which all participants have a sense of well-being is an essential element in a collaborative partnership among facilitators and students.

Considering the WAL's idiosyncratic lifestyle, we realize that along with the course outcomes, the most essential feature of online instruction is convenience - convenience of schedule, of course structure, assignments and interaction with the instructor. Convenience, in our view, is another iteration of customized learning. Nowadays customized goods and services tend to become more prevalent. The rigid traditional onsite format of higher education cannot provide this individualized instruction by definition. In fact, certain adult learners have not been able to access higher education due to the simple factors, such as inflexible scheduling and traveling distance from campus. This is why online students appreciate the new dimensions of time and distance presented in asynchronous online education. This does not mean online education is a simplified version of the traditional onsite experience. We are convinced online and onsite rigor and outcomes must be equivalent. Nevertheless, a comfort zone for the WAL can be provided in the course format through planning and organization that relies on adult learning theory specific to an online environment. For instance, convenience of schedule in online education is apparent in its flexibility (students work at their own pace at a time of their choice). Convenience in content delivery is provided by the availability of reliable and quality online learning resources with the professor acting as a gatekeeper (to assure an accurate and scholarly information base) for a variety of Internet resources. Another manifestation of convenience is the presentation of online course on the students' computers. The instructional process, assignments and evaluation should be very unambiguous. Complexity of learning should be not on the screen but in the communication between a student and the instructor (Ryan, 2001).

The ongoing transformation of online education in terms of the professor, learner, curriculum and specific methodological approach is appropriately enhanced by adult learning theory. In a sense, online education presents an exceptional laboratory experience that can produce a collaborative effort to construct a model that meets the particular needs of the adult learner. Rapport between the instructor, enlightened by adult learning theory, and the WAL is paramount to a successful online learning experience. Broadening access to online education opens up new horizons of opportunity for greater number of diverse adult learners than ever before.

STRATEGIC FOCUS / BLENDED LEARNING

Corporate Education – A new vision of training and development.

The current competitive scenario shows us a radical reduction in knowledge life-time, and companies perceived that they cannot depend anymore only on the traditional schools and programs to develop their employees.

In this way, some enterprises have chosen to improve their own educational areas, looking for a closer follow-up of the training processes, focusing on the company's necessities specifically. It is believed that the key for success is to provide to the employees a better access to the information, improving their knowledge and skills, giving the companies a real competitive advantage. All of this should be accomplished through results evidence.

In Brazil, companies need to establish a main unit responsible for sharing their vision, corporate strategies and for the management of the acquired knowledge. In the same way, there is also a pressure to focus training and development on the companies core business, as well as to demonstrate their return on investment.

However, there is no value for the best training program if the managers were not concerned about retaining this knowledge in the enterprise. Training people for the opponent is a very close possibility in the competitive world nowadays. So, Corporate Universities take place as an internal organization with the mission of developing people in the long term, attracting and retaining the best professionals, and also accelerating the internal knowledge flow.

Concerned about the same problem, Brasil Telecom has decided to use a blended corporate education model as the formula to focus all the development efforts, straight to the company's strategic objectives.

The targets for Brasil Telecom Corporate Education are all the business units, developing their leaders on the following subjects:

- Leadership;
- People management;
- Financial management;
- Marketing management;
- Telecommunication management.

To develop its activities, Brasil Telecom's Corporate Education uses both internal and external instructors. The partnership with external schools aims to establish contact with the best management technologies, as well as the best practices in the industry. On the other hand, the internal instructors will teach how the company works, spreading out their know-how.

At the same time, complementing all the courses, Brasil Telecom's Corporate Education uses also on-line distance learning tools, proportioning video-on-demand, web based training courses, on-line library, synchronous meetings, among others. The use of distance learning allows specific advantages, such as:

- offering training in a large scale, reaching all the value chain (customers, partners, suppliers);
- choosing the place and schedule for training sections - students have they own rythm;
- accelerating the knowledge acquisition and update;
- offering just-in-time training;
- offering a simple interface;
- offering a better control of the training process.

Concerning return on investment, Brasil Telecom's Corporate Education students, once selected, have the commitment of improving their areas results and optimizing the use of their resources.

The competencies developed by Brasil Telecom's Corporate Education are:

- *customer focus* (identify and preview what the customer needs and value);
- *leadership* (focus the strategies, the activities and the resources);
- *teamwork* (work as a team, considering the organizational goals);
- *continuous development* (create an environment for a continuous learning);
- *coaching* (motivate and influence people for a high performance).

Finally, Brasil Telecom's Corporate Education allows the company to centralize learning solutions, supplying the traditional education gaps, sharing the internal know-how, defining training standards and decreasing costs through the scale of contracting.

STUDENT PERFORMANCE ANALYSIS USING BIVARIATE CORRELATION FOR HIGHER ACADEMIC SUCCESS IN ELECTRONICS ENGINEERING PROGRAM

Gulden KOKTURK
Dept. of Electrical&Electronics Eng., University of Dokuz Eylul, Izmir, TURKEY
gulden.kokturk@deu.edu.tr

Guven SAGDIC
Dept. of Electrical&Electronics Eng., University of Dokuz Eylul, Izmir, TURKEY

Abstract: In this work, we established a statically connection between age, college entrance score and student performance, and between basic science courses of first year like physics, calculus etc. and student performance. We calculated this relationship using bivariate correlation analysis. For all data, score transformation was computed with linear transformation method. Data was extracted from undergrade classes in Electronics Engineering program. We investigated the student performance for all and classifying data with correlation analysis.

Introduction

Researchers and educators have been interested in determining factors related to student academic success. Student performance analysis has historically been used as predictors of school success by establishing correlation method in which to compare school achievement with similar schools.

The purpose of this work was to determine the effect of student age, college entrance score with relationship between them and average scales on student achievement courses. The courses examined in this work were as follows; physics I (first year, first semester course), physics II (first year, second semester course), calculus I (first year, first semester course), calculus II (first year, second semester course), chemistry (first year, first or second semester course), first year-first semester average scale and fist year-second semester average scale. The study question, therefore, addresses to what extent these student enrollment status are related to student grades in courses.

Bivariate correlation was used to analyze the relationship between the student enrollment status and last semester average scale, and between lecture grades and semesters average scales. This analysis examines the correlations between these items to determine the prediction of factors that best predict student scores.

There are several researches on correlation. Patrica Plympton et al. (2000) have recently proposed effects of daylighting on student performance. Sherry and Jesse (2001) were investigated student solving talent with correlation. Another research (Tinto, 1995) has been studied on overall degree progression of the students.

Bivariate Correlation

In this study, bivariate correlation analysis was conducted on several variables related to college student's demographic and enrollment status and their student grade performance. All data consisted of all students grades in courses, were extracted from the University's student record system. Specifically, as you known that status variables included age (in years), college entrance score, and grades in courses. Grades were obtained on a 4 point-to-point average scale. After data was analyzed, they were classified as first, second, third and last grades. Then correlation coefficients calculated for all and classified data.

As a simple fact that the correlation is association between two quantative variables (Borden, 1998). In this project, we used correlation for our maximum likelihood estimator (Mendenhall et al., 1990). It was seen that the correlation among some variables in the study is large in age than in the school entrance score. However, correlation between age and last semester average scale is small. Because of the positivity in it, age has smallest correlation with last semester scale. Calculus II score had the largest correlation with last scale. The positive correlation indicating that students had attained a math grades in their high school class tent to attain higher college grades. It is noted that first year-first semester and first year-second semester average scale is highly related with last average scale. This is indicated that first year-first and second semester courses are the most important in student achievement. For each class, correlation is presented for some courses in this work. It is shown the correlation of the basic courses grades with last average scale for each class. All correlation coefficients are positive. In this situation, the largest correlation is in physics course. When it is calculated the relation between age and entrance score with last average scale for class-to-class, age to last scale in first and second years of University life is negatively related with each other. This means that younger students tented to lower average scale.

Conclusion

Bivariate correlations demonstrated that variables; age, school entrance score, first and second semester basic courses, first year-first semester average scale and first year-second semester average scale were the most highly correlated with last average scale and all positive correlates. However, the two predictors which age and entrance score are negatively correlated in some classes suggesting that their impact on last average scale might be mitigated.

The statistical relationship uncovered in this analysis, is qualified by the very large sample size. That is the large size makes it possible to uncover very weak associations.

The Use of The Internet in High School and University

Nicoletta Sala
Academy of Architecture - University of Italian Switzerland
CH 6850 Mendrisio – Switzerland –
nsala @ arch.unisi.ch

Abstract The aim of this paper is to present two different experiences which involve the Internet in educational paths in high school and university. In first experience, named Web Learning Environment (WLE), we have studied the use of the WEB and its resources to develop a new learning environment. We have involved a classroom (sixteen students, aged 16-17) of a technical institute in Italy. The project has been divided in six different phases: the knowledge of the Internet, the research in the Internet, the access to the FTP, the didactics with the Internet, the communication using the "Net", and the creation of a cooperative hypertext dedicated to the Bonaventura Cavalieri (an Italian mathematician). Our second experience, named "Cybermath", is an attempt to build some hypermedia modules to introduce the fundamental of Mathematics in a undergraduate course. It has been developed at the Academy of Architecture of Mendrisio (University of Italian Switzerland), Switzerland.

First Experience: Web Learning Environment (WLE) Project

The computer technology and the Internet have become important parts of education across the curriculum and will likely be more so in the future. Innovative use of technology combines telecommunications (e-mail, online resources, Internet navigators), multimedia authoring (home page editors), user-friendly convenient applications software are modifying respectively the role of the teachers and of the students in the didactic environment (Sala, 1999; Sala, 2000). The role of the classroom teacher is evolving from that of a giver of information to that of a facilitator of student learning. The role of the students is more active than the last years. Our first educational project is an attempt to build in a high school an active learning environment using the Internet and the Web technologies. It has been divided in six parts:

1. the knowledge of the Internet (the students, organised in eight groups each composed by two persons, have learnt the Internet directly in the Web using some special interactive lessons, developed by the "Polo Didattico e di Ricerca di Crema" Italy, available at the Internet address: http://weblab. crema.unimi.it/ internetcourse/),
2. the research in the Internet (the students have learnt to use the search engines, for example: Altavista, Yahoo, Google, Vivisimo, comparing their performances using the same keywords),
3. the access to the FTP (the students have analysed the capability to download, to install and to use some shareware and freeware software dedicated to the mathematics, geometry, Italian literature, and information technology),
4. the didactics with the Internet (the students have used some educational Internet sites dedicated to the Italian literature, to the physics, and to the mathematics),
5. the creation of a cooperative hypertext dedicated to the Italian mathematic ian Bonaventura Cavalieri (our approach is also a "Learning by Doing", in fact the students have also learnt the history of mathematics during the hypertext development),
6. the communication using the "Net" (where a disabled student of our classroom has communicated with other European students using the e-mail).

Second Experience: "Cybermath" Project

Second experience involves the use of the Internet and its resource to build a hypermedia course of Mathematics in university (Sala, 2001). This course, named "Cybermath", intends to develop a propaedeutic course of Mathematics to introduce some particular subjects. This project intends to create an effective-based learning environment that provides synchronous and asynchronous education to learners who are physically remote. The aim of this project is to develop a distance learning model to introduce the fundamental of Mathematics, to permit to the students:

- to overcome the problems of the different background before the beginning of the academic year;

- to help them to reach a good grounding in Mathematics
- to overcome the strong dislike for this subject using a medium, the computer, which has a good communicative impact.

The environment provides: the user registration; the hypermedia lessons; the course materials; the tests online; some active links to other Internet sites dedicated to the mathematics. The hypermedia modules have been written using the DHTML (Dynamic Hypertext Markup Language) with the aid of Java Applet and JavaScript procedures to introduce multimedia codes (e.g. video clips, audio comments). We have also used Virtual Reality Language Modelling (VRLM) to create the virtual worlds and the virtual object (e.g. virtual polyhedra). Virtual Reality (VR) is a good medium, in distance learning, for making abstract concepts concrete, for example to touch or to manipulate virtual geometric objects and to observe their symmetries (Sala, 2002). Virtual reality can also help constructivist learning and this is an important aspect of distance learning (Winn, 1993).

Conclusions

The Internet provides a perfect environment for the learner to have access to many resources, to choose the exercises, to offer an almost similar educational connection with reality, to encourage learning and to create a constructivist approach in the learning (Postema et al, 2001; Sala, 1999; Sala, 2000). The Web is viewed as a solution for the global access of information (Collis, 1998). Our projects demonstrate that the Internet and the new technologies offer significant benefits in educational process, and they show that there are clear educational advantages to be derived from cooperative student activities. Inside our WLE and Cybermath projects, the role of the teacher is evolving from that of a giver of information to that of a facilitator of student learning. We have also noted that the students exhibited strong motivation in the hypertext development, and this is encouraging for the future application of the Internet and its resources in the educational process.

Using CMC to Build Middle School Communities Among Peers with Mild/Moderate Disabilities

"Email has swept the world during the last decade..." (Bikson & Panis, 1997, p. 1). Recent surveys indicate that middle school age children are its most prolific users (Quinn, 1998). Ditlea (1999) reports that net surfing adolescents are virtually "flocking to cyberspace" (p. 1), and apparently, "what they mostly want is to read each others' words" (Ditlea, 1999, p. 1).

This revolution emerged against the backdrop of a" proliferation of education reform efforts" ushered into American schools since the release of A Nation At Risk (Means, Blando, Olson, Middleton, SRI International, Morocco, Remz, Zorfass, Education Development Corporation, 1993, p. 1). Pundits of American schools, fueled by warnings in the report that the Nation's future and people were threatened by an erosion of educational standards, and, having witnessed the manner in which technology had transformed the workplace, advocated for the use of technology to support the kind of structural reforms in schools they believed necessary to improve the dire state of education as outlined in the report (Means, et al. 1993). In response, two trends developed that greatly impacted public schools today: (a) a proliferation of computer/technologies in schools, and related challenges to determine the best ways to utilize this technology; and, pressures for improving academic outcomes (i.e., statewide performance testing/CMT's, advanced academic courses). Recent events in schools across the nation (e.g., shootings of students and teachers, charges of harassment and an increasingly diverse school population-including students with disabilities) have also increased pressures to specifically improve social outcomes within school environments for all students.

The purpose of this paper is to explore the potential interface of these trends in the emerging phenomenon of computer-mediated communication. Computer-mediated communications, "(CMC) is a method of communication that uses a computer as a transfer medium permitting individuals to communicate without geographical or time restrictions" (Holden & Wedman, 1993, p. 5). Although computer-mediated communications exists in many forms, this review concentrates on two text-based CMC systems that have achieved ubiquitous acceptance: email and the World Wide Web [WWW] (Haythornthwaite, Wellman, & Garton, 1998), and evidence of its use in mediating social interactions among preadolescent middle school youth with and without disabilities. These students are faced with unique challenges in an increasingly dynamic and diverse school environment, hence exploring the potential use of CMC, particularly email as an intervention to establish and maintain positive social relations between them is important.

Technology, Teachers, and PT3

A progress report on a Department of Education PT3 (Preparing Tomorrow's Teachers to Use Technology) grant

Seeing is not necessarily understanding, when it comes to online lessons. In this seminar, real examples of actual online lessons are highlighted. The presenters demonstrate how PT3 faculty and support personnel did what they did – from incorporating text to Java applets and more.

In our PT3 project, we consider technologies (e.g., email, word processing, web course building, streaming audio/video, java applets, ePortfolios) based upon a number of factors, including ease of integration, cost, existing campus and departmental support, and potential impact upon teaching and learning. The examples illustrate a range of different types of course content in various disciplines, and demonstrate what is possible in the online environment.

We believe that technology-based interventions should be consistent with what we know about how people learn and what constitutes good teaching practice. Models for infusing technology into teaching can include strategies such as peer coaching, collaboration, mentoring, problem-based learning and modeling. In this presentation, we move from theory to practice, and demonstrate how technology can be implemented within proven teaching and learning models.

Attendees will be provided with a web address that contains the conference presentation as well as additional materials for their exploration when they return home.

Using Speech to Enhance a Math Education Applets

David B. Sher
Mat/Sta/CMP Department
Nassau Community College
1 Education Dr.
Garden City NY 11530
sherd@ncc.edu

This paper discusses a java package, called **talk,** that takes numbers (and in the future expressions) and speaks them out loud. The package is designed to run on a maximal set of browsers and is used by several applets as part of a precalculus education web site (http://www.polar.sunynassau.edu/~sherd/Applets/Calclet or http://www.calclet.com).

The reform approach to mathematics education is to present mathematical ideas with multiple modalities. Speech adds a powerful ability to mathematics education web sites. Speech allows applets to fully implement the rule of four (verbal, numeric, symbolic and graphical modalities) that forms the heart of the reform calculus approach.

I. Talk Package Design

This section discusses how to use the talk package from another java applet.

1.1. Sound Files

The sound files must be in the au format to maximize the set of web browsers that can properly present the sounds. A collection of sound files has been installed in http://www.calclet.com/Sounds/. The package expects sound files in a folder called Sounds in the same folder as the web page. So if the web page containing a talking was at location http://www.somewhere.com/mypage.htm a copy of the sound files would have to be at http://www.somewhere.com/Sounds/.

Sound files have been constructed to say any number in the author's voice. Numbers like fourteen are said by playing the sound file in 4.au to say four and teen.au to say teen. To use the talk package you need to copy all the au files in http://www.calclet.com/Sounds/.

1.2. Package Components

This paragraph describes how to use the components from a Java applet.

1.2.1. Copyright applet

The copyright applet does two things for the package. It says the copyright notice in copyright.au (in the Sounds directory) and will say it when the mouse is clicked on it.

Putting the copyright applet in the initial web page causes the talk package to load as the page loads, so that the other applets that use it can load it from cache rather than waiting for the package to download from the internet.

Its even more useful if other packages are contained in the jar file with the talk package. All of my precalculus teaching packages are stored in a file called everything.jar. By using the copyright applet all of the applets preloads while the users observe the initial page and decides which applet or applets they want to use.

1.2.2. Sayer class

Sayer is a thread that is used to organize and synchronize the words and mostly to prevent them from being said at the same time. Java 1.1's sound methods are rather primitive and if the play method of an audio clip is called when another audio clip is playing both sounds will be overlapped. The Sayer takes an audio clip and a number of milliseconds and waits that number of milliseconds before it plays another one. Each talking number creates a Sayer. You will not need to directly call the methods of this class.

1.2.3. talkingNumber class

This is the central class of the talk package. talkingNumber has methods to play integers, doubles, and strings containing any number. It can only handle numbers up to 999,999,999,999,999. It will ignore any digits beyond that. It can handle numbers in scientific notation and numbers with decimals.

It will also say certain words. It has the word "bleh" built in to indicate an error. It has the copyright message built in. It expects all the sound files to be in a Sounds directory that is under the directory containing the web page containing the applet.

You can change and add to the sounds in the Sounds directory or download them from http://www.calclet.com. You can add new words into this directory and use the talkingNumber's playWord method to play the word using a specified number of milliseconds. playWord("moose",700) will play the audio clip in Sounds/moose.au and give it 700 milliseconds to play. Recently I added audio clips x.au and y.au to help the package give coordinates.

The getDigitTime method returns the number of milliseconds to say a digit (approximately 1 syllable). This is useful for timing other words. You can also speed up or slow down the speech by using the setDigitTime method. Setting too small a digitTime may have unfortunate results.

1.2.4. talkingNumberSource class

A talkingNumberSource is a component that extends TextField and also runs stand alone. Basically any number written into that TextField will be said when an action is sent to that class (which is an action listener). Of course it also has all the methods that a TextField ordinarily have so you can put text in and either allow or prevent the user from entering text. This is an easy way to introduce talking into your applets and applications.

2. *Talk Package Use*

This section discusses how the talk package is used in the games package of http://www.calclet.com. From this other users can see how it can be used in their packages. Since this package was developed using support from the Department of Education and Nassau Community College, users of the package are requested to email sherd@ncc.edu so the dissemination of the package can be documented. The components of this package are copyrighted, but they are free for educational use. Anyone who wishes to use them for profit making software is requested to contact David B. Sher, the author.

2.1. Copyright

The copyright applet serves to download the jar file necessary to run these tools and to speak the copyright notice. Failure of this applet indicates some problem with the web site or browser (or maybe the operating system). When the applet runs it will display a copyright symbol, as shown in the red box in the figure below. Thus it is apparent, even on a muted computer, whether the jar files loaded.

Copyright © David B. Sher 2002

Copyright Applet running in web page

The main point of this applet is to download the jar file and the sound files into the cache before while the user is selecting which applet to run. http://www.calclet.com uses the applet for this purpose in the frame http://www.calclet.com/precalculus_games.htm.

2.2. Games and Drills

Many of the games and drills in http://www.calclet.com use the talkingNumber class to state the problem. If a game has a "Do Talk" button, pressing the button starts the applet talking. Usually there will be no speech until the game is started though. You can turn on or turn off speech during a game by pressing this button.

The default for the applets is no speech because speech slows down the applets. Computers better suited to multimodal processing may not experience this problem, which does occur on Pentium 200 with 64Mbyte RAMs.

Usually these applets refer to points in a coordinate system and the applet states the x coordinate and y coordinate of each of the points. Thus the problem is prompted verbally. Also verbal negative feedback is used when the user presents incorrect answers. In the future positive feedback will be added (and maybe some kind of encouragement for close answers also).

2.3. Modeling

In the economy modeler (and soon in the stock modeler) applets the talk package is used to present the difference between the modeling function and the data being modeled. Checking the talk check box, toggles speech. The applet won't say anything till a data set is selected and a modeling function is entered.

When the user enters a new modeling function the error of this function is presented verbally as well as in a TextField. Since the user is seeking to minimize the error this will focus attention on it. This focus is important for a complex applet with a lot of textual and graphical information presented.

In the future we will consider adding the ability the present the user's modeling function expression verbally too. This will avoid surprises, for example, parts of the function lying outside the visual area of the text field.

3. *Conclusion*

This paper presents a package used for adding speech to mathematics teaching applets and other applets with significant mathematical content. It has been successfully used in a package documented in http://www.calclet.com.

4. *Acknowledgement*

Development of Computer-Based Instructional System on Introductory Statistics

Minsuk K. Shim
University of Rhode Island
19 Upper College Road, Kingston, RI 02881

Sunguk M. Shim
South Kingstown High School
215 Columbia Street, Wakefield, RI 02879

Abstract

This paper describes the motivation and usage of interactive instruction developed for basic statistics education. It was developed to help students in introductory statistics courses better understand some of the more difficult concepts that they encounter. When students use spreadsheets to experiment and illustrate their problems, they can better visualize the problems and more easily see what happens. Interactive instruction with thirteen lessons may be found at http://www.soe.uri.edu/mshim/StatProject/.

Introduction

Students frequently view statistics as the worst course taken in college (Hogg, 1991) and a reform of introductory statistics classes has been advocated by many statisticians. Some believe that the goals of an introductory statistics course should be redirected from mathematical technique to data analysis (Cobb, 1991). Others advocate changes in pedagogy, replacing passively received lectures with hands-on activities (Bradstreet, 1996; Smith, 1998).

Functional skills in statistics are a basic requirement when students analyze data. Often those skills can be more efficiently learned by applying statistical concepts through statistical programs (Malthy, 2001). Familiarity with statistical programs provides students a chance to see how statistical concepts can be applied to understand and analyze real-life problems. The author has found that many students do not have easy access to statistical software at home. Many of them, however, have computers at home with spreadsheet software such as Microsoft Excel. This research first began with wondering whether students could use the spreadsheet software for statistical analysis, as they are more accessible and easier to use than conventional statistical software. The idea was then expanded to the development of a computer-aided, self-paced instructional system on statistics using Excel as it can give students more freedom to work when and where it would be most convenient for them.

Spreadsheets for Teaching Introductory Statistics

SAS (Statistical Analysis System) and SPSS (Statistical Program for Social Science) are the two most widely used statistical programs and the ones that are available on computer labs around campus. Although they are much more powerful in complex, high-level statistical analyses, they are often difficult to learn and expensive to buy for personal use. Spreadsheet software is easier to use, widely used, and now includes extensive statistical functionality (Nash & Quon, 1996).

Research also suggests that students studying functions using spreadsheets and graphing tools understand functions better than those studying functions in a more traditional manner (Dugdale, 1990; Magidson, 1992; Schwarz, Dreyfus, and Bruckheimer, 1990 [cited in Fyfe, 1995]; Zucker & Huntley, 2001).

Many states require students to begin using spreadsheets as early as grade 5. In Virginia, for example, students are required to obtain the minimum skills of creating simple databases and spreadsheets to manage information and create reports by the end of grade 5, and communicating spreadsheets by entering data and setting up formulas, analyzing data, and creating graphs or charts to visually represent data by the end of grade 8 (Virginia Department of Education, 1995).

Activities

Basic descriptive and inferential statistics are covered (descriptive statistics: mean, median, mode, variance, standard deviation, frequency, and reliability; inferential statistics: *t*-tests, analysis of variance, regression analysis, and Chi-square test). Thirteen topics that were relevant to the course were selected and multimedia self-exploratory lesson is being developed for each topic. Each lesson takes approximately 30 minutes. It explains how to manipulate the data set and use Excel functions for statistical analysis, and provides hands-on activities using sample data. Once it is fully developed, it can be used for many courses where statistical knowledge is needed. The detailed activities include:

- Creating the sample data sets for the basic descriptive and inferential statistics defined above,
- Creating the course modules using the sample data sets,
- Converting the course modules into user-friendly on-line learning format,
- Developing a web site to maintain and distribute the system, and
- Customizing the system according the users' needs.

Conclusions and Discussions

This research shows how the spreadsheet and multimedia tools (Macromedia Director and Flash) can be used in aiding the understanding of introductory statistics. After the relevant concept has been introduced and discussed in class, the tutorial is demonstrated and its pertinence to the concept is explained. Students are then asked to investigate the interactive lessons further on their own time and to analyze the sample data sets designed to guide their exploration of the concept.

On the whole, this computer-aided, self-paced learning tutorial was a success. It provided the students with the ability to complete data analysis with all the benefits of spreadsheet, without accessing the commercial statistical software. The students enjoyed using it and would like to see other topics covered in a similar manner. Most students became involved in the system and tried to analyze data with the spreadsheet. Although students' attitudes and responses toward this computer-based instruction haven't been surveyed yet, they seem to be very supportive to it. To take advantage of the full capabilities of this system, the next steps would be collecting students' feedback, adding more multimedia-rich instruction such as audio, and creating tutorial CDs as stand-alone executables.

A BLENDED LEARNING APPROACH to FACULTY DEVELOPMENT: USING the OR-CAT MODEL for the I3 TRAINING SERIES

Bernadette Sibuma, Mathematics, Science, & Technology Department, Teachers College, Columbia University,
New York, New York, United States. E-mail: bes2004@columbia.edu.

Due to the shift to economies of knowledge, universities face the challenge of rapidly creating distance learning programs while staying true to the values of higher education. At the heart of the university's transformation lies the relationship between the institution and its faculty. Faculty participation in distance learning initiatives, such as e-learning, is crucial to the long-term success of the program at the university. However, at present, there are mixed responses from faculty at many campuses about the development of distance learning initiatives. Debates focus on the traditional faculty-university relationship and seek to resolve how that relationship may be changed or maintained with the advent of distance learning programs. This project addressed the need to find successful strategies to foster faculty participation and commitment to distance learning initiatives at higher education institutions.

The majority of the project presents the OR-CAT instructional design framework and the Internet Infused Instruction (I3) series – a blended implementation method. To begin the project, the general development of e-learning as a distance learning technology was reviewed. Then the contextual issues surrounding elearning in higher education were researched, particularly the need for faculty participation in the university's integration of distance learning. Finally, a strategy was proposed to increase faculty participation by providing training and support in teaching with new instructional technologies. The elements of the OR-CAT instructional design model are: 1) Observe: A learner observes a simulated event or phenomena; 2) Read: A learner reads background materials and other resources about the event or phenomena; 3) Reflect: A learner reflects and communicates about what she has observed and read, connecting it to her own context or past experiences; 4) Construct: A learner creates a publicly viewable demonstration of her understanding; 5) Argue/discuss: A learner views others' reflections or constructions and "argues" with other participants about any differences in understanding; 6) Adapt: A learner revises her construction, based on the previous step; and 7) Transfer: A learner problem-solves a new situation in which the knowledge or skill can be applied. Based on the OR-CAT model, the proposed I3 training series incorporates recent information from the learning industry about elements found in successful blended learning programs as well as constructivist instructional design principles. In addition, Chickering & Ehrmann's (1996) work is highlighted as guiding principles for instructional technology integration at the university level.

Experts indicate that long-term committed involvement by the faculty in distance learning initiatives requires a coherent institutional strategy that shows genuine concern for faculty interests and development. One already identified area where the university may fall short is in faculty training and support in using learning technologies in their courses. By offering technology training such as the Internet-Infused Instruction (I3) series, the administration moves towards sustained support for distance learning initiatives from faculty as well as signifies the importance of the faculty-university relationship during a time of institutional transformation.

MathThread: Math and Distance Learning threaded discussions

Glenn Gordon Smith
Janice Grackin
David Ferguson
State University of New at Stony Brook
United States

Abstract: Distance learning web-environments do not provide the most basic communication tools for discussion of math problem solving vital to math courses. A needs assessment indicates that online instructors and students need to be able to view, edit, and post diagrams and formulas directly in online postings, without going through laborious intermediary stages. MathThread, an NSF-funded project, is dedicated to providing these tools to online instructors and students, supporting instructors in adapting their classes to use these tools and researching the effects of more natural math-oriented threaded discussion tools on mathematics learning. After reviewing the existing possible tools, we have formed a partnership with NetTutor who makes the Whiteboard math discussion tools. We have conducted a pilot study evaluating undergraduate students' ease of using the Whiteboard for calculus discussion. We found that most participants had little trouble understanding and using the tools.

Need

Current distance learning web-environments emphasize the written word and threaded discussions, but do not provide the most basic communication tools for discussion of math problem solving vital to math courses. In face-to-face math classes, instructors work problems, write formulas and draw diagrams on the chalkboard while students ask questions, providing a feedback communication loop. When students hand in homework, instructors and TA's can cross things out and write other formulas. This ability to demonstrate problem solving, represent problems through diagrams, and provide a communication feedback loop are fundamental to math learning, yet are awkward in web-based distance learning environments. Currently math notation, as well as diagrams, can not be directly included in online distance ed. documents. Because math notation and diagrams are NOT integral with the online distance education environments, instructors laboriously go through several steps to attach an image file with formulas and diagrams. Since students can not respond by writing math notation, this disrupts the communication loop. In a Sept. 2000 needs assessment of 40 web-based math instructors in N.Y. State using a dominant web-based environment, instructors declared, *"It has been extremely frustrating teaching math online..."*, and *"Your project sounds very timely and useful ."* Instructors consistently wished they could put equations, math notation, conceptual diagrams and graphs directly into online postings (i.e., a math notation editor, a drawing tool for creating conceptual sketches, and a graphing calculator).

Major goals, approaches, past and current work

In response to these goals, the MathThread group at Stony Brook University seeks to:

1) Provide distance ed. math instructors with basic math communication tools to fluently teach math, including direct inclusion of math notation, conceptual drawings and graphs into distance ed. postings by both instructors and students. Instructors will directly put math symbols into distance ed. documents, without converting documents into unmodifiable formats (such as image files, gif's, LaTex etc.) and adding them as attachments. Our goal is to have modifiable math notation in distance ed. documents, so instructors can easily copy, modify and annotate students' work and thereby achieve fluent of two-way math communication. *Achieve by:* Unite an existing distance ed. Environment with a math-friendly interface, NetTutor's Whiteboard, which creates, views and edits math notation and diagrams. 2) Adapt existing web-based and face-to-face college math courses to include these basic communication tools for math. *Achieve by:* Through the SUNY Learning

Network, a non-profit infrastructure for distance ed. at the State Universities of New York, redesign/deliver two Intro. Calculus and two Pre-Calculus courses using the math friendly communications tools. 3) Provide faculty development/support for instructors to re-design their math courses. *Achieve by:* During redesign of adapted courses, instructors meet with the project personnel and receive feedback on designing online math classes from other instructors at SLN, through online threaded discussion. 4) Research the impact of more natural math and diagrammatic communication on math learning. *Achieve by:* Once adapted courses are running in the SLN environment, research students' use of different modalities (e.g., diagrams, graphs, formulas) in their learning, for example, the correlation between diagrams use and comprehension/achievement, particularly for developmental students. 5) Facilitate the quick spread of basic math distance ed. communication tools to other math instructors a) in the Dept. of Applied Math & Statistics at STONY BROOK, b) within SLN through-out the state of New York and c) nationally. *Achieve by:* During redesign of adapted math courses, approach other math instructors at SLN for suggestions. Offer on-campus workshops through the Center for Excellence in Learning and Teaching (CELT) at STONY BROOK. Provide other math instructors with a simulation of a distance ed. math course using easy creation/viewing/editing of math notation, diagrams and graphs within assignments and discussions. During teaching of adapted courses, allow other math instructors to unobtrusively observe. Suggest that other math instructors use MathThread in one experimental unit. Present at the yearly SUNY Conference on Instructional Technology (CIT). Approach other distance ed. providers about using the basic math communication tools. Write papers for peer-reviewed journals and present workshops and papers at national conferences.

MathThread has adopted what is probably the best and most complete communication infrastructure solution for college math e-learning, the Whiteboard by NetTutor (www.nettutor.com). Whiteboard can also be used in asynchronous mode for math oriented threaded discussions. So far Whiteboard is the only working tool that allows users to put *directly* into asynchronous threaded discussions the most vital elements of math communication: formulas, graphs, and diagrams. There are no intermediary stages, just an interface that allows users to view, edit and post discussions with these elements. The NetTutor/Whiteboard could use some improvements on its interface. Since Whiteboard is the only reasonably complete and working product supplying the needs of math asynchronous threaded discussion, we have chosen Whiteboard as the tool we will use and they have agreed to a partnership with us.

The Math Thread project has recently been funded by the National Science Foundation, through the program Course, Curriculum, and Laboratory Improvement - Adaptation and Implementation (NSF CCLI A&I). The funding started January 2002 and runs for three years.

Prior to introducing the Net Tutor software into experimental classroom settings it is important to identify human and other factors (such interface design and technical usability) that might influence how well the software would function as part of a course. Early identification of such factors provides opportunities to modify or eliminate them prior to actual implementation, or to control for the identified factors in the experimental setting and account for them in subsequent project assessment.

A series of six pilot sessions were completed. Students who had taken or were currently taking pre-calculus or calculus were recruited to participate in single sessions to evaluate the use of the Net Tutor software in a naturalistic setting. Sessions were held in a computer lab, and students received course credit for their participation.

In general, responses to Net Tutor were relatively positive. Most, though not all, participants had little or no difficulty understanding how to use the tools ("It wasn't hard at all."), found most of them easy to work with, felt they had the right tools to do what they wanted to do, and felt there were enough tools provided. There also appeared to be a consensus that there was a certain awkwardness and tediousness to using Net Tutor, and participants suggested that they would feel more positive about the software if it functioned in simpler and more familiar ways. Most participants indicated that they believed they could become comfortable and proficient with the tools as part of a class in a fairly short time. The people at NetTutor have agreed to immediately address issues brought up in the pilot study. We feel that when these problems are fixed, NetTutor's Whiteboard will be a very serviceable tool for mathematics-oriented asynchronous threaded discussion.

The next phase in our project is to train and support several online mathematics instructors to incorporate the Whiteboard tools into their existing courses. We have made a partnership with a community college Long Island New York to convert a pre-calculus and a calculus class to take full advantage of the Whiteboard tools. The adapted courses will be offered Fall of 2002.

Automated Study Questions for Medical Students Using the Web

P.R. Smith and Virginia H. Black
Department of Cell Biology
NYU School of Medicine
550 First Avenue
New York, NY 10016, USA.
e-mail: smithp01@med.nyu.edu, blackv01@med.nyu.edu

Abstract: Study questions challenge a student's knowledge of a topic. They reinforce the knowledge s/he has of the topic and guide him/her to identify and fill in those areas where knowledge is weak. They provide a very effective tool for learning, but are "expensive" in time for the student to answer and for the faculty to respond to. To meet these issues we have developed a software framework to administer study questions using the web. Student responses sent to the server by a web form are analyzed according to script on the server and appropriate answers returned. An anonymous log is kept of each student response so that the analysis script can be debugged and refined. Our preliminary experience with a pilot program as part of the first year medical school course "Cell Biology of Tissues and Organs" (Histology) is described here.

Introduction

Study questions are an effective way for the student to test his/her current level of knowledge. In the past, we have given the students a set of questions for each unit in the syllabus for the course "Cell Biology of Tissues and Organs" (Histology) (Black, 2002). Students referred to lecture notes and to the textbook in order to answer the question and then went to members of the faculty to get a critique of their response. While effective, with increased pressures from the curriculum, this approach may not be the most efficient use of student and faculty time. We therefore looked to see if a useful part of the study question paradigm could be delivered via a web-based tool.

Software was developed that provides a very general framework for the administration of questions to students in a study (rather than an examination) setting where the identity of the individual student is not an issue. We expected that automation would be well received by the students since most have had previous experience with computers and all are required to own one.

Software Implementation

The aim of the software development was to develop a tool that was simple to use, fast in execution and highly flexible. One of the criteria was that the software should be able to analyze free-text responses from the students, and be able to work with questions created with check-boxes, radio buttons, etc, which are used as common components of web forms.

We chose to build the tool, which is called KEYSEARCH, as a traditional cgi program activated by the standard web forms interface (HTML Forms, 2002). In operation KEYSEARCH is activated to accept the data posted from the student's web browser by way of a response to the study question. KEYSEARCH then reads a file containing the specific script that directs the processing of these data. The computed answer is returned to the browser and a log of the transaction is written to an HTML (HyperText Markup Language) file to be reviewed by the faculty member responsible for the particular question to which the student had responded.

The author of a study question has three tasks: first, the web page has to be prepared by defining the form that solicits and then posts the student answer to the server. Second, the "Response Logic File" (RLF) that directs data processing must be created. Finally, the log of student responses must be reviewed continually so that any scripting errors in the RLF can be found and corrected and the analysis of student responses refined.

The core of KEYSEARCH is the RLF that contains four types of control lines; these are Logic lines, aRithmetic lines, Answer lines and administration lines that customize output and define processing controls.

Logic lines define logical variables (L1, L2, ..., Ln) that store the result of a keyword search of the response the student has provided. An example of a L-line might look like this:

```
L1: 2; endomysium; perimysium; epimysium;
```

In this case, the variable L1 would be true if any two terms in the list were found in the student response.

aRithmetic lines evaluate logical expressions written in "Reverse Polish Notation" (RPN) (Ralston & Reilly, 1993) and are used with Answer lines which specify part of the answer to be returned to the student's web browser. An example of a pair of R- and A-lines might look like this:

```
R1: L1, L2, A
A1: Excellent! You identified connective tissue sheaths in muscle.
```

In this case if the logical variables L1 and L2 were both true then R1 would be evaluated as true ("A" is the **AND** operator) and the A-line paired with the R-line would be sent as part of the answer to the student. Complex expressions involving many L- and R-lines can be built to provide the resources to generate a nuanced answer, sensitive to the student response, and more valuable to the student than bald "true" / "false" statements.

The manual for KEYSEARCH, providing the full details of its implementation, is available on-line (Smith, 2002).

Preliminary Results

To test the potential value of KEYSEARCH the faculty of the Histology course committed to provide at least two study questions suitable for programming for KEYSEARCH in each of twelve topic areas. By the end of the course nearly 100 questions had been prepared, either as modifications of existing questions or as new questions. The types of questions were predominantly those that required free text input with the remainder (15-20%) being based on check-box or radio button selections similar to the multiple choice exam questions they would face.

The results for the course overall were very encouraging. KEYSEARCH logs appeared to show that for several topic areas over one third of the class (of 160 students) attempted to answer the on-line questions. The sets of questions used most frequently were in those topics that had most questions available and included questions that queried areas emphasized in lecture. Even the least-accessed questions were used by 15% of the class. It was interesting that for most study questions, students were willing to work at submitting a response that would cause the program to give the faculty answer.

The outcome of the test was judged a success. A range of question formats was prepared at a reasonable level of sophistication, sometimes driving improvements to the software. Conversations with students indicated that if they tried the questions they liked them: they worked differently from other on-line teaching materials and they enjoyed that.

Discussion

KEYSEARCH has two novel features: the ability to automate study questions where the student provides a free-text response, and a powerful logical expression analysis engine to power the creation of responses specifically targeted to the details provided in the student's answer.

The experience of the faculty with free text responses to study questions has always been that such questions require more thinking on the student's part and therefore work best as study materials. This anecdotal observation is supported by studies that have shown that multiple choice answer components may act as cues to the student elevating their performance (Newble et al., 1979).

The experience gained through the past year's course indicates that the "logic engine" provides a valuable tool to prepare study questions and that the students like the result. The KEYSEARCH logs verify that in many cases students think hard and work to improve initially unproductive answers to the study questions. This is exactly what was wanted: learning is an active process occurring inside the student's head, not inside the computer.

THE LINKS PROJECT:
DEVELOPMENT, IMPLEMENTATION, AND INSTITUTIONALIZATION

Sharla L. Snider, Ph.D.
Department of Family Sciences
Texas Woman's University
USA
ssnider@twu.edu

The purpose of this poster presentation is to provide an overview of the Learning and Integrating New Knowledge and Skills (LINKS) technology project and related research findings. This initiative was designed to integrate established and emerging technologies into the teacher preparation program at Texas Woman's University (TWU) and is supported by a U.S. Department of Education, Preparing Tomorrow's Teachers to Use Technology (PT3) grant. The LINKS project encouraged institutionalized efforts by prompting change in university faculty involvement and roles; technology curriculum content and delivery, and preservice teachers' performance and responsibilities in field-based locations.

Over three years, approximately 300 future teachers each semester have progressed through university coursework, technology seminars (now incorporated as coursework requirements), documentation of proficiencies in a Technology Passport, and field-based placements. Implementation and outcome data for events involving preservice teachers have been collected. As Intern Is and Intern IIs, the preservice teacher cohort participated in technology seminars, bi-weekly conferencing groups, and completed the Technology Passport. During Residency, preservice teachers began their student teaching and attended technology seminars on campus. Preservice teachers completed pre- and posttests each semester to assess changes in technological proficiency and use, as well as attitudes and concerns. Parametric paired-samples t-tests and effect sizes have been utilized for analyses of quantitative data for students with complete data sets. In addition, preservice teachers completed evaluations at the end of each semester to assess the utility and quality of their experience.

Each year, a volunteer sample of university instructors participated in professional development sessions primarily focused on an orientation to LINKS resources, technology expectations for preservice teachers, and the preparation of web-based course delivery via the university's web-based course delivery template. Overall, more than 75 university instructors from various disciplines have participated in LINKS activities. For year 3, data were collected on 23 instructors' stages of concern, levels of use, and perceptions of the utility and quality of training. In addition, a representative sample of faculty (7 instructors and 1 dean) participated in interviews to give feedback on LINKS involvement, technology proficiency and use, and the impact of LINKS on the institutionalization of technology at TWU.

Results and Conclusions

In fall 2001, 64 Residents completed the LINKS curriculum sequence. This cohort will be the last group finishing the teacher education sequence under the old certification plan. Overall, results reveal that Residents consider themselves more technologically proficient after experiencing LINKS activities, with statistically significant pre- and posttest differences for all domains of the Basic Computer Use and Internet Use, and on 2 out of 7 domains on Advanced

Computer Use. Preservice teachers moved toward higher impact concerns and relatively low self-concerns as measured by the SoCQ. Qualitative analyses revealed generally positive acceptance of and comfort with technology, as well as confidence in curricular integration of technology.

In year 3, LINKS preservice teacher activities have been redesigned as courses that are university teacher education requirements. This revised format involves interdisciplinary collaboration for the education of preservice teaches. New certification plans that include a technology component have been implemented in fall 2001. LINKS preservice teacher activities were redesigned as university teacher education course requirements. Prerequisite technology proficiency standards have also been established. This revised technology-driven format involves interdisciplinary collaboration and institutionalizes the integration of technology proficiencies for preservice teachers.

A growing cadre of university instructors have been oriented to the technology needs of preservice teachers and introduced to online course delivery via LINKS training and activities. More than 75 instructors have either participated or received support from the LINKS center. In May 2001, additional activities were implemented for faculty beyond the PT^3 proposed grant to institutionalize LINKS activities. Faculty were given training through an INTEL grant—Teach to the Future. Participating faculty then redelivered training to Residents and their supervising teachers in fall 2001. This enabled LINKS to systematically integrate the Intel curriculum into teacher preparation. In addition, in summer 2001, LINKS collaborated with TWU to provide summer training institutes for 12 faculty in online course development. LINKS activities have also been extended to the post-baccalaureate teacher preparation program. Through a unique mentoring approach, 5 experienced faculty (with extensive LINKS training) functioned as mentors and expert facilitators for 5 university instructors developing post-baccalaureate courses. Additionally, the LINKS faculty training and support was redesigned in year 3 to encompass a series of 17 training sessions across the academic year. The 23 participating faculty received support from the LINKS team either individually or online.

Preliminary findings point to factors contributing to institutionalization, including the integration of LINKS resources with other university initiatives, the inclusion of diverse disciplines in LINKS activities, ongoing communication between LINKS staff and university administrators, the exceptional quality of LINKS activities and products, and a constant focus on sustainability of grant efforts.

Educational Importance

Findings regarding the implementation and effectiveness of LINKS project have implications in at least three specific areas. First, results will demonstrate how technology proficiencies of entry-level teachers can be increased to address state and national expectations. Next, findings will also show how university professors can be supported as effective models of technology use in web-based course delivery and electronic communications with students. Finally, the LINKS experience provides a model for universities undertaking similar changes in teacher preparation programs. The LINKS web site provides a number of project-related resources, such as the Technology Passport, that are available for use by other institutions. Documentation of learner-centered standards for preservice teachers through the Technology Passport provides a much-needed accountability model for monitoring and assessing changes in preservice teachers' technological proficiencies in relation to established standards.

DEVELOPING AND VALIDATING COMPETENCIES FOR CLASSROOM AND ONLINE TEACHERS

Abstract: The International Board of Standards for Training, Performance and Instruction is completing a three-year effort to develop and validate competencies for classroom and online teachers. This effort is partly an update to the previous set of standards for classroom instructors, but is aimed specifically at exploring new competencies that are required in technology enhanced settings. The focus of this presentation is the relationship of skills and knowledge for online instructors (broadly interpreted to include web-delivered as well as hybrid settings) vis a vis those required in a traditional classroom. Data were collected from approximately 1,000 respondents worldwide representing a variety of contexts and settings. Several expert panels were held in addition to the survey. Problems in conducting such a large online survey will also be discussed.

Introduction

The mission of the International Board of Standards for Training, Performance and Instruction (***ibstpi***) is to improve individual and organizational learning and performance, and in doing so to promote the quality and integrity of professional practice. Among the activities of the Board have been the development, validation and revision of sets of competencies pertaining to the performance technology community, including competencies for instructors, instructional designers, and training managers.

The Board has been engaged in a three-year effort to update its instructor competencies. Associated with this project was an effort to develop an accompanying elaboration of competencies for those who conduct training in online and hybrid settings that mix some classroom instruction with online and other forms of technology -enhanced learning and support. The Board's process for competency development begins with an extensive review of current literature and practice and expert panel meetings (Collison et al., 2001; Cyrs, 1997; Goodyear et al., 2001; Kearsley, 2000; Pea, 2000; Salmon, 2000; Spector & Anderson, 2000; Thatch & Murphy, 1995). From these data, the Board drafts an initial set of competencies and then elaborates associated performance statements that serve as indicators that a person has or lacks a particular competence. The draft set of competencies is then submitted to a large international audience for review and comments.

BEST COPY AVAILABLE

Development and Validation of the Competencies

In the development and validation of competencies for classroom and online teachers, the process was significantly more complex and challenging. Lengthy discussions, debates and forums addressed the issue of how classroom and online instruction were related. The Board's initial position was that practice of instruction in classroom and online settings were sufficiently different to warrant separate sets of competencies. As the Board's empirical work evolved, it became evident that there was much overlap at one level of abstraction while specific ways that competency might be demonstrated still differed in classroom and online settings. Moreover, the emergence of blended instruction - a kind of technology integration that makes use of hybrid delivery means to achieve various instructional objectives - underlined the need to explore the extent and nature of the relationships between classroom and online instruction (Spector & de la Teja, 2001).

The Board drafted competencies in five areas: Professional Foundations, Planning and Preparation, Instructional Methods and Strategies, Assessment and Evaluation, and Management. Associated with 21 competency statements in the initial draft were 126 performance statements. To validate the competencies, a web-based survey was created to assess the respondents' level of agreement with each of the competency and performance statements in face-to-face, online and blended learning environments. A paper-based version was also available for those without Internet access. Extensive demographic data were also collected to determine the respondents' workplace, teaching background, educational level, area of the world so that detailed analysis could be conducted. The survey was then sent to training institutions, professional organizations, and worldwide contacts in training and teaching, distance education institutions.

This presentation will highlight the use of MOT, a knowledge modeling tool developed at LICEF research center in Montreal, allowing the graphic representation of the relationship between competencies in online and classroom settings. In addition, this presentation will focus on the empirical findings and an initial analysis of an extensive international survey. Finally, several issues will be discussed, including the need to address competencies for learners in both classroom and online settings, and worldwide cultural differences found.

The Konstanz Internet Solar Cell Experiment

Martin Stachel, Department of Physics, University of Konstanz, Germany, email : ms@lockin.de

Abstract : Due to the strong interest in the physics and technology of modern solar cells, even outside of universities and research labs, the Advanced Physics Lab of the University of Konstanz, Germany, is making efforts to make accessible its Solar Cell Experiment to an interested and qualified public over the internet.

Basic Ideas

In view of the augmenting hazards of power generation from fossile combustibles, electric power generation from regenerative energy ressources, especially from solar radiation, by semiconducting solar cells, becomes increasingly important. The investigation of new light sensitive materials and improving the quantum efficiency of known solar sensitive material, like Si, is a challenge for physicists and engineers worldwide.

In order to familiarize our physics students with this topic, we have built up a Solar Cell Experiment at our Advanced Physics Lab, in close co-operation with the renowned Materials Research Lab at the University of Konstanz. In this experiment, the students have to investigate the important parameters of differently manufactured and contacted Si solar cells : their dark and bright I(U) characteristics, respectively, as well as the quantum efficiencies as a function of the energy of the incident light.

Due to the general interest in solar cell physics and technology, not only with our students but also with "external" people and even with the upper classes of high schools, considerations were made how to open this experiment to an interested and qualified public. Since our Advanced Lab was among the first labs to offer, and to work with Virtual Internet Experiments worldwide (Stachel 98), and for reasons of our experience from this work, making the experiment, or parts of it, accessible over the Internet was suggesting.

Here, in contrast to the above mentioned "virtual" experiment, work and interaction of the user with remote real physical devices and instruments "anywhere in the world" is necessary. This interaction, as well as a mediation of the "look and feel" of the experiment, has to be performed over the Internet, a new challenge for people involved in teaching experimental experience.

Due to our experience with the previous virtual experiment, the programming work was again made in Java, in this case with special use of the Java Native Interface, in order to remotely control measuring instruments, or cameras. In this way, the whole technical task of the interaction between experimenter and remote instrumentation may be performed by means of "pure Java". This procedure has the advantage that no special ("proprietary") equipment on the experimenter's side is needed : a standard "Java 2" enabled Internet browser is sufficient to work with the experiment, a fact to be considered well with regard to the intended audience.

Overview of the Project

The "local" experiment at the Lab is divided in two parts :

1. Measuring and analysing the different I(U) characteristics, as well as calculating the overall efficiency of the cells from these data.

For this purpose, our sun simulator at the moment simply consists of a low voltage halogen lamp. Since the solar spectrum at the surface of the earth has an intensity maximum at about 450 nm, with continuous decrease to larger wavelengths, the red and IR parts of the halogen spectrum are reduced by a KG-3 filter. A substantial improvement of the resultant data is expected from using a metal halide discharge lamp which has a spectrum much closer to the sun's as compared to the "heated filament", resistive halogen lamps.

2. Investigation of the differential quantum efficiency of Si solar cells.

For this part, the equipment consists of a xenon discharge sun, and a prism monochromator for wavelength selection. Since the cells' efficiency is very low below 450 nm and in the vicinity of the Si band gap energy (above 900 nm), to determine the cells' output current, lock-in measuring methods have to be applied. At this point, our Virtual Lock-In Experiment (Stachel 98) is generally of great help for students new to this – commonly used but rather sophisticated, and thence, in general, poorly understood - technique.

Experts will probably agree that this experiment "by itself" is rather complex and demanding, even if carried out locally. To make it accessible over the Internet adds further problems to the system which have to be solved successively.

Status of the Internet Implementation

At the moment of this writing (August 2002), the first part, as described above, may be performed in parts over the net (Stachel 02). Since only one user at one time may be allowed to work with the experiment, "time slots" of about half an hour are allocated in which the experiment can be accessed by a password. This password has to be applied for by means of a registration form on the experiment's home page. If appropriate time slots are at disposal, depending on local or further Internet use of the equipment, the password is issued via email.

After logging in, the experimenter may select one of the solar cells available, set several measuring parameters (voltage span to be covered in the characteristic, number of data points, and the time interval between the measurements), and the "Sun's" condition.

If the dark characteristics are to be taken, the settings are sent to the experiment server over the net, the voltages calculated from these params are applied across the active system (solar cell plus series resistor) by an DA converter, and the corresponding current is measured by a DA converter as a voltage drop across the series resistance. At this point, the Java Native Interface comes into the play.

The complete data set is sent back in list form to the user, and are displayed as a I(U) graph, on-line. In the graph area itself, the students have the possibility to draw the maximum power rectangle necessary to calculate the efficiency of the cell under investigation. The IU data measured may be saved on the experiment's server and be retrieved later by ftp for further analysis or documentation.

If bright characteristics are to be taken, the experiment sun has to be managed, too. In the case of the halogen lamp, its proper function is tested by the resistance, or voltage drop caused by a constant durrent, of a light sensitive resistor. If the sun is ok, the UI data are taken and handled as above. If the sun is "burnt out", a respective message will be displayed on the experimenter's monitor, and the measurement is cancelled.

In the case of metal halide discharge lamps, it takes a little bit of time until a stable light emission is achieved after starting the discharge. This procedure is also monitored by a light sensitive resistor in the experiment. The "ok", or "sun failure" statuses are sent back to the experimenter so that he/she may, or may not, start the mesaurement.

As to the "look and feel" of the experiment, two approaches are being tested :

The user is given the choice to select a "still background scenery" consisting of a set of three large images showing the whole experimental setup in its "fundamental" three states, with normal lab illumination, with the sun on and off, respectively. It is possible for the student to „navigate" around in the images, as with a camera, to zoom in and out, to look at details or to get an overview. The user can identify the instruments and parts used in the experiment and follow the connections between the devices and instruments, and compare his/her observations with the given setup schematic.

The other choice is the use of a webcam controlled over the internet for online visual inspection of the experimental scenery. This may be more appropriate when working with the "discharge sun".

As in our previous virtual experiment, support for the remote student may be obtained via email communication which has proved to be a generally sufficient solution for any experimental, or understanding problem.

Phillip Diol
Department of Industrial, Interior, and Visual Communication Design
The Ohio State University
United States
diol.16@osu.edu

Abstract: As educators, designers, engineers, and authors, we are all trying to fully understand the nature, potential, and appropriate application of the WWW. There are many different skill sets trying to claim ownership to the medium of web design. To satisfy the technical, functional, cognitive, communicative, and aesthetic demands of web site design, a convergence of our collective expertise will be necessary. A synthesis of principles from the fields of design, human-computer interaction, computer information science, cognitive psychology, engineering, and marketing has merit. We believe that through the understanding and application of these interdisciplinary concepts, designers will consistently deliver sites that are visually appealing, stimulating, easy to learn and understand, easy to use, efficient, useful, and empowering. This paper/poster explores relevant interdisciplinary curricular issues, and how they can be appropriately integrated to teach web design from a holistic viewpoint.

Introduction

Interactivity is the fundamental principle underlying the growth of communication between users and responsive systems delivered via the World Wide Web. Given the constraints of structured curriculum, how then do we appropriately integrate the rapidly emerging field of web design into our teaching? Additionally, how do we fully prepare students for the dynamic nature of this design activity? In order to make optimum use of this medium; one must be grounded in the issues relevant to those concepts that distinguish the medium.

As the bodies of knowledge, and breadth of web applications continue to expand in our various disciplines, how do we appropriately integrate the instruction of web design into current design curriculum? One strategy may be to look to our companion disciplines for structure, and guidance. Web design is an application that crosses several curriculum boundaries. Valuable theoretical principles from design, human-computer interaction, computer information science, cognitive psychology, engineering, and marketing can and should be applied to web design pedagogy. To design web sites from a holistic viewpoint, web design educators must begin to embrace the idea of interdisciplinary methodologies, principles, and concepts. An examination of the relationships between these inter-related disciplines may prove useful in structuring a process for understanding and teaching web design and adequately preparing students.

Presentation

Because web sites are manifested as a visual and interactive medium, its incorporation into visual communication design curriculum is a logical one. In order to design web sites that are optimum for users, one must be grounded in the issues intrinsic to the medium. Furthermore, students who study "web design" in a siloed environment do not always have a core set of skills necessary to be competitive and productive and a highly dynamic field such as this. Those students who are employed find that their education continues when they join the professional ranks. The employers must continue to guide and instruct their designers on issues relating to appropriate visual problem solving for screens, programming language, interaction and interface design, site architecture, usability, and new and developing authoring tools.

Our research has indicated that a synthesis of principles from the fields of design, human-computer interaction, computer information science, cognitive psychology, engineering, and marketing have merit. It is our intent to integrate these concepts into a more formal area of study within the discipline of visual communication design at our institution. We believe that through the understanding and application of these interdisciplinary concepts, designers will consistently deliver web sites that are visually appealing and stimulating, easy to learn and understand, easy to use, efficient, useful, and empowering to users.

By examining the areas that define and distinguish web design, several relevant concepts are realized. Having an understanding of these concepts, and then applying them at appropriate levels of the design process, can begin to yield web applications that truly meet or exceed the expectations of users. The following figure outlines the range of disciplines that we believe makes up the core competencies needed for entry-level web designers and authors.

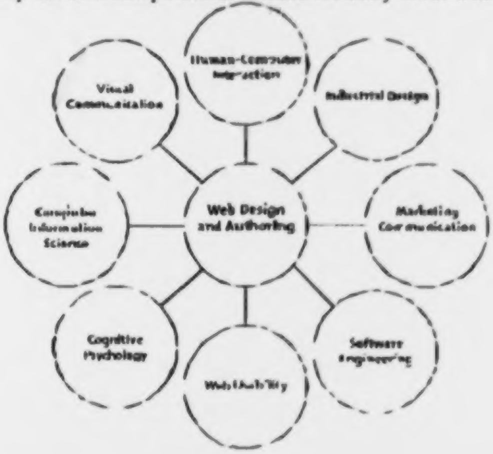

Figure 1: Core competencies for web design and authoring

Once these similarities are recognized and understood, a meaningful design process can be outlined. A typical process model is as follows:

1) Identify the problem / needs
2) Research past and present solutions
3) Planning / concepts
4) Develop prototypes
5) Usability test
6) Choose and refine
7) Acceptance test
8) Refine
9) Implement
10) Evaluate

Conclusions

Our research explores the relationships between these interdisciplinary curricula, and how it can be appropriately integrated to teach web design from a holistic viewpoint. The study looks at the similarities of design process and activity between these interdisciplinary models, and outlines important considerations for teaching web design. Through this research, we proposed a curriculum plan for four-year undergraduate design programs that prepare students with the needed skill set, which in turn, will allow recent graduates to distinguish themselves in the immerging field of web design and authorship

E-Learning and International Education:
Fulfilling the Promise of the Virtual Classroom

Introduction

This brief paper will present the history, pedagogy and design of an innovative online course, Qualitative Research in Education, that is currently being offered through the International Education Department and the Distance Learning Project at Teachers College, Columbia University. This exceptional course brings to the forefront the expanded educational opportunities made possible by online learning and the Internet. International learning communities comprised of students and professionals, virtual work and study teams, and the focus on an authentic education project form the basis for the design of this course. Online learning is the mechanism that makes this type of education possible.

History

Each year the course Qualitative Research in Education is taught in the International Education Department at Teachers College, Columbia University. The focus of the course is evaluation of educational projects using qualitative research methods. The course is constructivist in nature. The students evaluate a real education project in collaboration with a participating national or international non-governmental organization (NGO). Past participating organizations include but are not limited to: The International Rescue Committee, New York, The Anti-Defamation League, New York, Teachers Experiencing Antarctica and the Arctic, Mongolian Foundation for Open Society, the U.N. Association of the U.S.A. and the Soros Foundation, Latvia. Two years ago, the professor of the course, Dr. Gita Steiner-Khamsi decided to offer the course online. The online component allows for direct participation of the international NGO partners.

Educational Partnership

In the Spring 2002 semester the course took another innovative step. Prof. Steiner-Khamsi and Mr. Hugh McClean of The Open Society Institute (OSI), Budapest, Hungary developed a plan for an educational partnership between Teachers College and the Open Society Institute network in Eastern Europe and Central Asia. An initiative of the Soros Foundation,

> "The Open Society Institute was established in 1993 to promote the development and maintenance of open societies around the world. OSI does this by supporting an array of activities dealing with educational, social, legal, and health care reform, and by encouraging alternative approaches to complex and controversial issues."[1]

The Open Society Institute has offices throughout the world. The Budapest, Hungary office is the regional headquarters for Eastern European and Central Asian national OSI offices. Mr. McClean had identified two needs in relation to the national OSI offices in his region: 1) the need for effective evaluation of the educational projects being developed and implemented; and 2) the need to develop the local capacity for professional evaluation in these national offices. A huge emphasis in international education is the development of local capacity. In the past, international education specialists have failed to transfer their knowledge to individuals in the local community. As a result, first world funded educational initiatives for the developing world would fail once the educational specialists left the country. Training personnel in the developing host country is key to the success of educational initiatives in these countries.

Recognizing the need to develop professionals with great evaluation skills in the national OSI offices in his region, Mr. McClean and Prof. Steiner-Khamsi created the plan to enroll 16 OSI professional staff members in eight Eastern European and Central Asian countries in the Qualitative Research in Education course. Sixteen matriculated Teachers College students would also be enrolled in the course.

This cohort of 32 students presents a unique opportunity for all involved. The OSI professional staff members are receiving crucial professional development that will strengthen the effectiveness of their respective national education projects. These professionals are also enjoying the experience of taking a course with a well-respected internationally known scholar (Prof. Steiner-Khamsi) at one of the premiere education graduate schools in the United States, Teachers College, Columbia University. The Teachers College students have the opportunity to work in the field with professionals on real education projects. Many of the Teachers College students hope to establish careers in educational evaluation upon graduation. The opportunity to gain hands-on experience in their chosen field is significant. The benefits to students enrolled in the class cannot be overstated; they are not only learning the content material of the course, but also gaining valuable experience in cross-cultural communication and online education.

Instructional Design

The course has a unique organization. In addition to the blend of students, professionals receiving professional development and students developing content area knowledge and receiving hands-on experience, the course utilizes three modes of pedagogical presentation: 1) four face-to-face week-end seminars (two in Eastern Europe and two in New York City); 2) Online course presentation including online lectures, discussion boards, virtual chats, virtual team meetings, videos and tutorials; and 3) A week long onsite visit of the educational project being evaluated. Also, a videoconference session occurred between all participants on April 12th.

---

[1] http://www.soros.org/osi.html - Copy taken from web site on 04/06/02 at 10:33am.

The students work together in virtual teams. There are eight team consisting of four members each, two teachers college students and two OSI professionals from one of each of the eight countries represented. The eight participating OSI national offices are:

- Azerbaijan
- Georgia
- Kazakhstan
- Moldova
- Romania
- Slovakia
- Ukraine
- Yugoslavia

Each team works to evaluate an educational project that the respective OSI team members have selected in their countries. The virtual teams meet two to three times per week in the synchronous chat rooms online to plan the details of the evaluation and to discuss course material and readings presented in the online class. The whole class has a virtual chat once a week and there is also an ongoing discussion in the whole class asynchronous discussion board.

Blackboard was used as the online course platform. The technical affordances of Blackboard were used to the fullest in this class. A second level of navigation was added in the course documents section of the site. This allowed the professor of the course to organize and disseminate the extensive course materials. The lectures were presented in PowerPoint presentations that could be run from the server or downloaded to an individual computer and run from the local drive. Extensive Internet resources were linked throughout the PowerPoint lectures. Students were presented not only with lectures and links, but also given access to specific freeware tools for doing qualitative research. Blackboard's group pages section was used to create special group pages for each of the eight virtual teams to work. Each team had its own discussion board, virtual chat area and file exchange, all of these tools were frequently used. Introductory videos explaining the history of the course as well as the genesis of the project were created and uploaded to the site. Videos covering the unique pedagogical and technical aspects of the class were added, as was a video outlining the professor's expectation of the students.

The onsite visits occurred during the week of March 14-March 21, 2002, spring break for the Teachers College students. The Teachers College students traveled to the host country of their OSI counterparts and together the virtual teams collected qualitative data with which to conduct the evaluation. The cost of the onsite visit was borne by the Soros Foundation.

Another unique aspect of the course was the participation of three instructors. The course was co-taught by Dr. Gita Steiner-Khamsi and Dr. Cathryn Magno, adjunct assistant professor of education at Teachers College. Mr. McClean, participated in the course as a content expert and attended the face-to-face seminars and participated in the online discussions.

Student Satisfaction

Brief interviews undertaken during the semester with a small number of both the OSI cohort and the Teachers College students revealed a deep satisfaction with being part of such an innovative educational experience. According to these students, virtual work team communication is the most challenging aspect of this type of experience. Cross-cultural communication in an online medium logically presents special problems. Prof. Steiner-Khamsi designed the face-to-face seminars and the onsite visits as a means for participants to communicate with one another and to facilitate the creation of a learning community.

EVA_pm: Towards Project-Based e-Learning

Daniel.Schneider@tecfa.unige.ch

Abstract: EVA_pm, is a method and at the same time a constructivist web-based environment that has as it's main goal to scaffold Project-Based e-Learning in higher education. More precise, it focuses on improving the effectiveness of pedagogical models that are based on projects (usually called Project-Based Learning, project method or project approach). It leverages XML (eXtended Markup Language) and suggests a rich vocabulary (DTD) for the project/research plan as a prompting and reflection tool. Moreover, an online toolset ("commNcontrol") is provided for teamwork, visualization, communication, peer benefits and progress tracking. Finally, a second vocabulary is provided for the final paper on the project and dissemination of the project products is being done through a portal that is called "Virtual Book". This is an ongoing study and current results will be reported here.

Introduction

Project-Based Learning (hereafter PBL) is a constructivist instructional model that organizes learning around projects i.e., complex tasks based on challenging questions, that involve students in design, problem-solving, decision making or investigating activities and give them the opportunity to work autonomously and culminate in realistic results. According to several studies (reviewed in the PhD thesis of Thomas, 2000), organizing learning around projects is considered to be a profitable learning strategy. In higher education, it is very often the case to ask students to conduct projects and almost always studies end with a big project like diploma work, thesis, etc. *Still, its implementation faces several challenges.* Very often, students face difficulties such as initiate inquiry, define the research project, direct investigations, manage time, collaborate and give feedback, and follow-up the project. For all the above reasons, several studies have concluded that the method needs support and that the projects have to be well structured (Guzdial, M., 1998 refers to "scaffolding" and Scardamalia, M., et al., 1999 to "procedural facilitation") and several computer environments were developed to provide that (CAMILE, CSILE, PBLSS, Design diary, Reflective learner, etc.). While most of them were focusing on a specific problem, EVA_pm tries to scaffold PBL through all it's phases. The primary objectives of this study are: a)help students acquire *methodological competence* through support for the research plan, b)support students acquire *professional competence* on the subject of the project, c)help them acquire social competence by teamwork and d)develop *meta-cognitive skills* by reflecting on the work done. At a second stage, it aims also in making *students more efficient* and the method *affordable for tutors*. To do the above, this study uses structured text (in XML format) as a cognitive tool and a web and java based environment as the project's portal; to scaffold students to construct basic knowledge on research design, to get a project done, to reflect on their work, to disseminate results, to facilitate the tutor's role and enjoy the peer benefits.

The EVA_pm Environment

EVA_pm is formed by four components: 1)*EVA_pm ML*; an XML grammar (DTD) for project design that is used as cognitive tool to scaffold students during the projects, 2)*commNcontrol*; a web portal[1] that provides several tools to support the method like awareness tools, versioning system, file transfer tools, discussion tools and tutor evaluation tools, 3)*Virtual Book* ; the web portal[2] that joins the results of the projects (papers) and plays the role of the socio-constructivist "product" element by giving the chance to the students to expose the common result of their work, 4)*EVA_paper ML*; an XML grammar (also a DTD) for the paper that describes the results of the project, serves as cognitive tool and help students reflect on their work. These components are orchestrated in the following way: students have to describe their project (specification and management) by editing an xml file that follows the EVA_pm grammar in several phases; that file should be uploaded and shared online through a versioning system with the other members of each group; viewing and interactions can be done through the "commNcontrol" portal where students and tutors can log in; tutors can scaffold and give regular feedback using the system; the project culminates with students writing a paper that describes the product (also as an xml file) and an online "Virtual Book" is being created with all the papers produced. Development was based on principles of participatory design and specifically of cooperative prototyping. From XML technologies the DTD and XSLT+FO have been used. JAVA servlets technology and Xerces Java parser (SAX and DOM API) from Apache Project was used for scripting and parsing the XML files. EVA_pm is the result of four years work of the authors on this project, and has been initially conceived for the course on "Teaching and learning in Virtual Space" of STAF diploma at TECFA, University of Geneva and it has always been tested with those students. The most complete study (Master thesis of Synteta, 2001) has been done with staf-2001 students (12 students=9 men and 3 women, 8 projects=4 from pairs and 4 from individuals). The course was organised around several phases and was in mixed format (one week in presence and 4 weeks by distance). There are three things that have been evaluated, the learning environment (usefulness and ergonomics), the students learning on research design and the tutor's facilitation.

Conclusions

The initial goal of this research was to develop an environment that would improve PBL efficiency by providing more scaffolding and that would structure carefully all the phases of a project in order to overcome the most common pitfalls. For the *learning environment*, we could say that the grammars are mature and the toolset quite powerful. The interface though could be improved concerning usability and more features could be added to improve interaction. For the *students learning*, and using a qualitative analysis approach (monitoring, evaluation of projects and comparisons with previous years, interviews and a case study), the results of this research show some evidence that there is profit at all stages that were targeted. For the *tutors*, whom their contribution to the success is invaluable, there is evidence that EVA_pm scaffolds their role in PBL and facilitates monitoring, feedback and evaluation tasks. Lack of powerful XML editors is the weak part for the moment of the method, and students need to be trained in order to work with XML grammars. Based on the above preliminary findings, EVA_pm has a lot of potential in it but there is also a lot of research that rests to be done yet. Currently, for this ongoing project, we are working in the design and development of an integrated portal that will include EVA_pm as a module among several other modules that are needed to construct a course that is based on Project-Based Learning.

Abstract: MECCA using Blackboard's CourseInfo (Bb) has demonstrated the export of "best practices" and collaborative administration of a summer Science enrichment program for high school students between two institutions of higher education. Accepted Students were paired with faculty mentors to do research, participate in online academic study, and prepare online research posters. Student evaluation demonstrated the strength of using e-learning tools with problem-based learning. F2F content delivery techniques in a virtual classroom were found to be educationally non-stimulating. The integration of problem-based learning with e-learning needs further study. Bb was used for administrative collaboration. Collaborative tools associated with Bb were mapped to administrative purposes, and used effectively.

Background

An important criteria for writing "good" proposals for high school student summer enrichment at research institutions of higher education is the export potential of the program as a model for other institutions to emulate. The MYS program represents our attempt to exchange best practice scenarios between two health science institutions who both have previous experience with summer enrichment programs. The conduit for this exchange was the integration of e-learning and computer/network mediated communication (CMC) tools provided by MECCA and UTHSC. Previous Young Memphis Scholar programs (YMS 1993-1998) at UTHSC provided students with a summer research experience and academic enrichment including a computer/network program provided by MECCA. The goal of the YMS program was designed to encourage predominantly minority students to follow academic career paths in math and science. The 9-12 CERTL (Center of Excellence in Research Teaching and Learning) Research Program at WFUSM was similar to the YMS program, but the academic components were absent. However, the goal of encouraging minority students to follow career paths into math and science was the same. YMS student evaluations showed us that providing a relevant academic experience between grades 9-12 was difficult if the focus was on specific disciplines such as math, chemistry, or biology. What was academically good for 12th graders was not always appropriate for 9th graders and visa versa. However, their MECCA computer experience and their research experience always received a higher evaluation from the students at all levels. Their computer/network experience taught them to use CMC tools and to present their summer research projects using web-based documentation. This was exciting for the students and relevant to their research experience.

Study

The MYS program accommodated up to 30 students/summer (2000 and 2001) split between both institutions. Students applied to this program via web-based forms. The MYS program, different from the previous YMS program, included only science curricula neutral to grade levels. We also eliminated paper-based research presentations (YMS programs) in favor of online web-based presentations. The new academic components of the MYS program were provided by instructional staff from both UTHSC and WFUSM using Bb e-learning tools. Virtual research posters were presented using the web server and other resources from the MECCA "Networking Infrastructure for Education" program. By changing the venue of academic offerings to capitalize on student interest in using network resources and by focusing on their interest in using web tools for their laboratory research presentations, we hoped to effectively join and extend this program into one of added enrichment for the students. Two virtual Bb communities were established for this program, an academic community of students, and an administrative community of program directors. For the first year, Bb classes included the Philosophy of Science presented online by faculty at UTHSC, and Life, the Universe and Everything (Astronomy) provided by faculty at Wake Forest Universities' main campus. For the second year, the Philosophy of Science was retained, but the Astronomy class was replaced with Problem Solving in Science using problem-based learning. Since much of e-learning is about collaboration, tools associated with this medium also provide the necessary components for an administrative collaboration. Therefore, we utilized various parts of the Bb environment to jointly administer the MYS program. At the conclusion of each program year, students were required to provide an online poster of their summer research projects. These virtual posters were evaluated (using International Science Fair guidelines) by members of our joint advisory board. Three students from each location were selected to present their research via teleconference to both groups in distance education classrooms. An MYS program evaluation was presented as a survey in Bb and collected from the students to assess the efficacy of the various parts of this program. The model for this evaluation was provided by CERTL at WFUSM, and it was altered to evaluate specific areas of the MYS program. There were four types of questions asked: 1) the general likes or dislikes the students may have relative to the program as a whole (multiple choice), 2) specific questions about each area of the program relative to the programs stated objectives (multiple choice), 3) general information about the student, and 4) questions requesting the students free comment about the program (short answers). Most of the information was obtained via multiple choice questions giving the students a choice of at least two degrees of positive, two degrees of negative, and one option for a neutral response. To score this information, each positive response was given a positive number starting with the least positive response being "1" and the second or most positive response being "2". The same scaling was true for the negative responses, but they were given negative numbers rather than positive numbers. A neutral response was set to "0". For each possible answer of each question, the percentage of students responding in that manner was reported from the Bb survey. The percent student response for each answer was multiplied by the number assigned to this answer and then multiplied by the number of students responding to the question. This provides a "total" student response to each item of every question. This total response was then divided by the maximum possible response for all the students responding to get a total percent positive or percent negative value for the question. These values were then plotted for each multiple choice question. The minimum and maximum possible response is –100% and +100%. Student evaluation of the general aspects (five questions) of this program was between 80% and 43% (2000), and 62% and 43% (2001). General aspects were related to the interactive nature of this program as a whole. The most significant changes between the first and second year was that the response to the question about how much hands-on activity they participated in went down from 76% to 64%, and the question about how much problem solving activity they participated in went up from 45% (2000) to 69% (2001). Responses to questions concerning specific subject areas of the program indicated that their research experience was 64% (2000) and 58% (2001), their computer experience 31% (2000) and 43% (2001), their Philosophy of Science experience was 30% (2000) and 24% (2001), their Astronomy experience was 29% (2000), and their Problem Solving in Science was 61% (2001). The two subject areas with the highest student ratings were their research experience and their Problem Solving in Science class. The non-traditional nature of the Problem Solving in Science class using the problem-based learning techniques was exciting and challenging to these students. More problem-based learning techniques implemented with e-learning environments may improve student retention and performance in online classes. Additional studies integrating e-learning with problem-based learning is needed. E-learning platforms such as Bb provide excellent collaboration tools that can be effectively used for remote program administration. We have successfully demonstrated that using these network tools make possible the export and administration of exemplary summer enrichment programs between multiple institutions. Sufficient prior instruction for using these tools to collaborate and administer is essential.

Algorithm to Evaluate Educational Effectiveness of Teacher's Advice in Multi-Media Assisted Education System with Individual Advance

Motonori Tamaki, Tsuneo Kuwabara, Kouichi Yamada, and Toshinao Kokubun
Access Service Network Systems Laboratories
Nippon Telegraph and Telephone Corporation
Japan
mtamaki@ansl.ntt.co.jp

Abstract: An algorithm is proposed to evaluate teacher advice messages in the Multi-Media Assisted Education System with Individual Advance (MESIA). MESIA is used in combination with a Computer-Assisted Instruction (CAI) system as a mentoring support system. Using MESIA allows teachers to provide efficacious support to stalled students during learning via CAI in real-time (Tamaki, 1998). The algorithm can evaluate the educational effectiveness of a teacher's advice messages that have been sent to stalled students to help them in their learning experience. The results of this evaluation are given teachers. Because of this feedback, teachers can recognize whether or not their advice was effective. Moreover, teachers can share these results on MESIA, thus enabling effective advice given to stalled students to be utilized by other teachers to derive the same benefit. Furthermore, these results can be used to evaluate a teacher's support skills.

Introduction

We have been developing a computer-based education support system named the Multimedia assisted Education System with Individual student Advance (MESIA), which supports teachers working with Computer-Assisted Instruction (CAI) in real-time (Tamaki et al., 1998). By using MESIA, teachers can observe students' learning progress and the results of examinations or questionnaires, and provide efficacious support to stalled students who are learning with CAI. Although conventional mentoring services in e-learning respond to student's questions within 24 hours, MESIA can not only answer these types of student questions in a few minutes but also send advice message that is actively fitted to a student's current state of learning.

In this paper, we describe the algorithm for evaluating a teacher's advice that is used in MESIA. The algorithm can evaluate the educational effectiveness of a teacher's advice message sent to stalled students. The results of the evaluation are given to teachers so that they can determine whether or not their advice message had been effective, thus, enabling them to easily offer new advice to similarly stalled students by reusing advice message for which the effectiveness has already been determined. Furthermore, teachers can share these results in MESIA, hence, they can learn how to offer better advice from the advice message of other teacher. In addition, these same results can be used to evaluate a teacher's instructional skills.

Algorithm to Evaluate Teacher's Advice

When a student reaches a plateau in MESIA, they are sent many words of advice from their teachers. Although a student can answer test questions correctly after being given advice from their teacher, it cannot be said that this advice was necessarily educationally effective. Since the student may be sent an advice message that is very like the correct answer to advance them from their stalled state, they can easily answer correctly questions related to their course-ware. Therefore, it is difficult to evaluate the educational effectiveness of the advice. In an attempt to tackle this problem, we developed an algorithm to evaluate the effectiveness of advice given by using the final examination to solve the above-mentioned problem of determining the effectiveness of advice offered.

Figure 1 shows the architecture of MESIA that is used to evaluate the educational effectiveness of advice offered to stalled students by their teachers. Students can study at their own pace using the CAI function. The Stalled-Student Identification function (SSI) analyzes the student state of learning, such as the time spent on a study item, answers to questionnaires and student's questions to teachers; and thus identifies the stalled students. This function is a red flag that alerts teachers of those students who require their attention. The final examination assesses the ability of students after they have studied an entire CAI course. Final Examination Score DB is a database to store final examination scores. The above functions, questionnaire content, and a database are used in the current version of MESIA.

Looking at things from the teacher's side, the Support Database (SDB), Relevance Database (RDB), and Advice Evaluation Function were added to evaluate the efficacy of a teacher's advice offered to a student via MESIA. When a teacher has sent an advice message to a stalled student, the advice *A* and the stalled student's leaning state *S*, such as the position of the student's stalled item in the course, answers to questionnaires, and questions submitted to teachers; are stored in the SDB in pairs. If a student has become a plateau and SDB had a same state *S* as his state. MESIA would send advice *A* paired with the state *S* to the student automatically.

Figure 1. Architecture of MESIA to evaluate effectiveness of the teacher's advice

The relevance of study items in-course and final examination's sub-questions are found in advance and are stored in the RDB. When a teacher has sent his advice to a stalled student, the advice and the sub-questions on the final examination pertaining to the stalled student's study item are stored together. Then, the effectiveness y_m of advice m is given by the following equation.

$$y_m = \sum_j \left(\frac{\Re_j}{Y_i \cdot K_j} \right) \qquad (1)$$

Item i is the study item in relation to which advice m was sent, and sub-question j is a sub-question of the final examination. When sub-question j relates to item i and the student answers sub-question j correctly, $\Re_j$ is set to 1. In contrast, $\Re_j$ is set to -1 when a wrong answer is given, and $\Re_j$ is set to 0 when sub-question j does not relate to item i; Y_i is the total number of advice messages sent in relation to item i; and K_j is the total number of items relevant to sub-question j. Equation (1) divides the result of sub-question j by the contribution of advice relevant to sub-question j. Therefore, each effectiveness value regardless of sub-question j is given by divided point $\Re_j$ in relation to item i and sub-question j by the total number Y_i of advice messages for item i and the total number K_j of sub-questions relevant to sub-question j.

Finally, the effectiveness y_m of advice m is calculated by total effectiveness regardless of the number of sub-questions. In practice, advice m is given by averaged y_m by the number of students, etc.

Summary

We proposed an algorithm to evaluate the educational effectiveness of a teacher's advice given to students participating in computer-aided learning. By using this algorithm, teachers can determine the level of effectiveness of their advice to stalled students in a learning program, create advice messages easily by reusing advice messages previously found to be effective, and learn how to develop effective advice messages by using the record of other teacher's advice messages that is kept in a data base. In addition, these the system can be used to evaluate a teacher's instructional skills. MESIA is being used for distance-learning at the central training center of Nippon Telegraph and Telephone East Corporation. Four thousands employees have already received MESIA-based training in the company.

Teaching for Social Justice: A Portal for Educators

The aim of this Intercultural and Cross-Cultural Teaching Portal is to establish communities of reflection and practice for diverse educators in P-12 educators who are teaching or preparing to teach in an educational environment. By coming together, we share our commitments and concerns as we review and recapture our experiences in facing challenges of educating everybody's children. We wanted to create spaces specifically where individuals of the same racial/cultural/ethnic backgrounds to communicate with and learn from each other. We also encourage intercultural and cross-cultural communications among teachers of different racial/cultural/ethnic groups. We raise questions such as how our cultures shape our vision of children's teaching and learning in general. More specifically, how our social and cultural identity helps to mold our interactions within the classroom.

The purpose of these forums is to facilitate discussions on multicultural education and social justice issues that may arise in classrooms and school communities. We realize that some groups feel more comfortable sharing with individuals whose worldviews are somewhat similar in nature. Although, we recognize that everyone bring a different set of values, attitudes and beliefs, we believe that some educators will feel more comfortable sharing in their own racial caucus group. Therefore, our position is that we develop racial/ethnic caucus groups so that, for example, Asian American educators who are teaching in intercultural and cross-cultural classroom environments can share their experiences as Asian and Asian Americans. We are interested in hearing from and engaging all educators nationally and internationally who are working in intercultural and cross-cultural school environments.

Our goal is to provide a forum where all educators are heard and their voices are liberated. We provide each forum where each group can share and express concerns within and across racial/ethnic and culture groups, as well as, a general forum for everyone. While anyone can enter any forum, we hold a position that each group be allowed to share comfortably based on their worldviews.

Facilitating Critical Reflection and Discourse in Online Master's Degree Programs

Presenters:

Evie Tindall, Ed.D.
Associate Professor
Regent University
evietin@regent.edu

Deanna Nisbet, ABD
Assistant Professor
Regent University
deannis@regent.edu

Problem Statement

As online degree programs flourish throughout the world, the need for critical reflection and discourse is increasingly evident. Without this type of scholarly engagement, students in online degree programs miss the vital transformational experiences that comprise the essence of teaching and learning.

What We Have Done

To address this problem, the presenters are developing and evaluating an instructional process intentionally designed to foster transformational learning experiences through critical reflection and discourse. The development of the instructional process began with a review of our educational philosophy. Next the key terms were defined, and current theory was examined. From this conceptual framework the instructional process emerged.

The review of our educational philosophy revealed three salient themes related to transformational learning:

- Two ways of knowing: intuitive and cognitive (heart and mind)
- Two dimensions of the learning process: autonomy and interconnectedness
- Multiple ways of constructing knowledge

Key terms were defined as follows:

- Critical Reflection: attentive consideration, meditation, contemplation, evaluation, and appreciation.
- Discourse: mutual interchange of thoughts, ideas, and concepts
- Transformation: substantively altering the present condition, or passing from one state to another.

Examination of the theory base encompassed the areas of critical reflection, discourse, and transformational learning.

The instructional process that emerged is as follows: (a) identification and examination of worldview, (b) critical reflection, (c) discourse, (d) synthesis and evaluation, and (e) extension. This instructional process is being evaluated through student products.

Why the Work is Important

Historically in traditional face-to-face programs, critical reflection and discourse are known as key processes in fostering transformational educational experiences. The challenge of online educational programs is to produce comparable depth and richness in learning in order to equip the great historians, philosophers, novelists, scientists, statesmen, etc. that are needed in our modern world. Our instructional process is an initial attempt to address this challenge. As presenters we look forward to the opportunity to interact with and receive feedback from other distance educators and researchers.

Key Components of the Poster/Demonstration

The poster/demonstration will consist of a display board, handouts and a laptop computer. The display board will be divided into three parts. The conceptual framework (themes, definitions, and theory base) will be displayed in the first section. The problem, instructional process, and accompanying student products will be found in the next section. Implications for practice, in the form of "Seven Tips for Facilitating Transformational Learning in an Online Environment," will be displayed in the third section. Handouts detailing the instructional process will be available. On a laptop screen, participants will be able to review examples of individual applications and group interactions.

Integrating Virtual and Face-to-Face Education in Computer Programming Learning: an Experience Using High Technology Classroom

Romero Tori
Escola Politecnica
Universidade de Sao Paulo
Brazil
tori@acm.org

Alberto Araujo Lopes
Faculdade Sumare
Brazil
aberto@alopes.com

Abstract: This paper reports and discusses an experiment in Computer Programming Learning, based on integrating virtual and face-to-face educational techniques. The main purpose of the experiment was to combine distance education tools and face-to-face education techniques, taking advantages from both kind of education. This experience took place at Sao Paulo, Brazil, within a Computer Science Course held by Sumare College, where classrooms are provided with high technology equipment such as electronic boards for teachers and electronic online desktop for students. The results reported here were focused on how the used techniques improved the student motivation for the course, and how the tools and techniques turned teacher work easier. The data was collect from a one-semester period.

Experiment Environment

Our experiment took place at Sumare High Education Institute, in Sao Paulo, Brazil, where up-to-date technology in classrooms is available, for both teachers and students. Today at Sumare, a typical classroom is equipped with a computer, embedded in the desk, for every student and for the teacher, each of them with Internet access via the Local Area Network (which connects virtually all computers of the institution). The teacher in each dassroom has a set of additional tools for helping him during class time: a multimedia video datashow can project on the whiteboard the actual screen of the teacher computer, allowing him/her to demonstrate, present and interact with digital information. Typical available applications are multimedia presentation software, internet browser and software development tools. The teacher can blank the screen at his/her discretion, switch the image source between computer and VCR, and even use the remote controller as the computer mouse. There is also an "electronic marker", working with a movement capture board attached to the whiteboard, which can be used as the mouse (in a very natural way), and for capturing what is written by the teacher. Finally, there is a webcam and microphone installed in every room, so that there is live video feed to the Internet, which can be viewed by authorized remote students.

On the software side, the following software resources are offered:

- personal network account and storage area for each student and teacher, accessible via Web
- online library resources
- online student services
- online teacher services
- biometric class attendance control system
- online learning tool (WebCT [WEBCT.COM, 2002])

The computer science students also have a webserver and a SQL server available for assignment production.

Observed Facts

After the experience period, the following observation could be collected from participant teachers:

Class Dynamics: teacher was ableto demonstrate the software creation and tool usage techniques, also creating the example files at class time with student interaction and participation, and instantly sharing those files.

Communication: students with low or absent personal communication skills to be able to express themselves more efficiently. Teacher-to-student communication improved, the teacher could be reached more frequently at off-class hours; schedule problems diminished

On-Class Student Behavior: some attention dispersion problems occurred: sometimes, students preferred to access the Internet or other online tools instead of participating in the class if the subject got difficult. The use of online quizzes was also somehow turned not viable because of absence of fraud control schemas;

Motivation: students got consistently more motivated because of the use of electronic tools; use of them were many times asked by them.

Teacher work: digitalization of hardcopy documents involved more class preparation time for the teacher, while creation of new material got faster. The use of e-mail and bulletin board systems required more off-class work by the teacher. That was also the case when using online quiz tools: there were more preparatiown time, but less or no evaluating time (the latter in the case of quizzes composed only by multiple choice questions).

Comments and conclusions

Since in our case we are talking about a young institution, founded in the year 2000, the integration of technology into the curricula is something natural, for the college already brings in its DNA the genetic code of technology, and the projects of its courses were developed under that perspective. In the Computer Science course, in which the experiment reported in this paper was developed, the active and collaborative learning, based on projects, and facilitated by technology, is the basis for its pedagogical project. The teachers who joined our team are all much motivated by the use of technology inside the classroom, as well as by the fact that they count on a support team that, among other activities, offers updating courses to teachers from time to time.

Within the new possibilities of application of technology on learning, we have been searching for solutions for a better learning of computer programming techniques, a topic that reveals itself as one of the biggest barriers to the students at the earlier phases of the undergraduate courses on Computer Science [Mainente, 1999].

The results of the experiment showed that integrating online and face-to-face techniques may be a motivating change for the students, as well as a way for the teacher to use time in a more efficient way.

Several improvements on the tools and techniques will be made for the related environment. There are tools being continuously developed to enhance teacher-student and teacher-course coordinator communication. Also, the Distance Learning group uses the collected experience data to envision new techniques to be proposed for the participant teachers.

Virtual Spaces of Cooperative Experimentation
Virtual Laboratory of Kinematics

Gonzalo Alberto Torres Samperio & Gustavo Núñez Esquer
Autonomous University of Hidalgo State,Information Technologies and Systems Research Center, México
torres@uaeh.reduaeh.mx gnunez@uaeh.reduaeh.mx

Abstract: This work introduces the concept of Virtual Spaces of Cooperative Experimentation (VSCE) as a generalization of the concept of Virtual Laboratory. A VSCE is a virtual environment that gives Internet oriented experimentation, developed with Virtual Reality techniques, with a Workgroup Model based on Instructional Planned Design. As a study case, there are three experiments developed in a Kinematics' Virtual Laboratory (to carry out the experimental work is required to understand friction or frictionless uniformly accelerated motion) namely: free fall, inclined plane and parabolic shot, with and without friction. The system presented constitutes a platform to solve problems in a cooperative environment which can be improved with new functionalities through the integration of new modules.

Introduction

Virtual reality is one of the most excellent Internet's advances of the last decade. This is in charge of development of three-dimensional computational environments, with interactive modeling techniques interacting one or several people (ISO/IEC 14774-1, 1997), (Burdea, 1994).

Virtual classroom is one of the concepts used when referring to Internet on-line teaching. In first instance, a virtual classroom is a teaching/learning environment supported by computers with a communication system (Adell, 1997). Virtual classrooms, are computer generated spaces that model or reproduce didactic environments of real classrooms, in contexts where is not possible to have participants physically reunited in a teaching/learning process. Laboratories, libraries, corridors, coffee shops and other virtual spaces plow being developed to you simulate yourself personal interaction in those ambient (Adell, 1997), (XML, 1999).

The concept *Virtual Laboratory* is one of the most relevant examples given for educational modality. Virtual Laboratories represent an interesting and revolutionary instrument for Computer Aided Education, since they can construct a whole intellectual exploration system conceived to increase speed of the learning process (Banks & Moon, 1997), (XML). Virtual laboratories can be a complement of conventional laboratory to make experiments which cannot be carried out in other way.

The concept of Virtual Spaces of Cooperative Experimentation (VSCE) introduced in this work, is a generalization of virtual laboratories that considers the use of interactive three-dimensional scenarios developed with virtual reality modeling techniques, where users can carry out planned experimental work in a cooperative environment. The proposal of VSCE is inspired by the concept of Learning Virtual Spaces (EVA) (Guzman, Nuñez, 1998). VSCE is centered in the development of virtual spaces for the experimentation and workgroup given by EVA.

Virtual Spaces of Cooperative Experimentation.

In VSCE, a cooperative experimentation model is developed for interaction among users, and those with professor. The knowledge of the area are ordered based on a Instruccional Planned Design, (Englewood, 1996), (Dick & Carey, 1978) which contemplates the cognitive processes, the learning objectives and the instructional strategies (see figure 1). Communication through Internet, allows collaboration and assistance getting in contact to each user with others in the same level or with professor (Rodriguez, 1999). Distributed experimentation, allows different users to carry out cooperative experimentation in simultaneous way in the same scene. With this outline, users execute cooperative experimentation tasks by manipulation of three-dimensional objects in a virtual space, shared with other users located in different geographical places. However, and although is taken as part of the pattern, the distributed experimentation is not implemented in the current version.

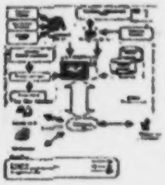

Figure 1: Virtual Spaces of Cooperative Experimentation.

Information about individual and group registration activities, carried out in the system are registered in the database, as well as the specific resources of the applications, such as initial simulations, experimental observations or experimentation activities are registered in the database.

Evaluation is an VSCE's important part, it is taken as a fundamental element to improve the quality of knowledge and

BEST COPY AVAILABLE

considers, in integral form, all tasks the student carries out, such as group work, carried out consults, experimental work, etc.. In this process, all learning elements for student are counting. Evaluation is considered individual because it is focused for each student and it is continuous, because has to be considered in student's record during the whole process. In the current version, individual evaluation is implemented.

Model of Cooperative Experimentation.

The proposed cooperative experimentation model, is looking for problems identification, and their possible solutions, carrying out activities in those that ideas, are expressed freely and summations are gotten by participants discussion or voting [25], (Ellis, Gibss & Rein, 1991).

The workgroup is moderated by a person which proposes a schedule that should be followed during instruction. The same person has the responsibility of meeting administration, specifying strategy to use in each stage assigning tasks and their responsible. On the other hand, participants carry out activities or commended tasks to be evaluated counting participants of the whole group (Hang, Lin, 1987), (McGilly, 1996).

Workgroup is ordered in sequential stages based on the use of strategies for presencial work that allow distributed interaction among users. These strategies (Brainstorm, Cognitive Maps, Quality Circles and Delphi), [25], (McGilly, 1996), (Hang, lin, 1987), (Ellis, Gibss & Rein, 1991), are implemented using available Internet communication basic tools; namely, e-mail, discussion forums, electronic boards and chat. Figure 2, shows the way strategies are integrated to cooperative experimentation.

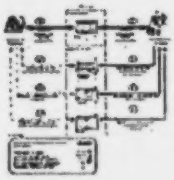

Figure 2: Implementation of workgroup strategies in communication services.

In this work, strategies have not been used just the way they have been described, but rather one of our own one has been generated taking some of the most excellent elements of the mentioned strategies. Proposed strategy is oriented to participants carry out activities and cooperate with each other in a natural way, to solve as better as possible the outlined problems.

Summary (Conclusion).

VSCE's model, defined in this work, incorporates, to Virtual Laboratory concept, the use of three-dimensional scenarios and a instructional planned design in a workgroup model context. Environments as presented in this work are not very common in Internet. With the VSCE concept is possible to develop interactive experiments for workgroups in several fields of knowledge. System developed in this work is a contribution to remote experimental work through Internet.

The cooperative experimental work design developed for VSCE uses workgroup strategies incorporated in experiments' instructional design. The system introduced constitutes a platform which can extend its functionality capacity through new tools, modules and heterogeneous systems integration and can be resized to solve problems in a cooperative environment.

Title: Education in an Era of Digital Competition: Gist and boundaries

By: Kiran Trivedi, Lecturer, EC/IT Department, S.S.Engineering College, Bhavnagar, Gujarat, India **Email**: kittuad1@sancharnet.in,

Abstract: *The purpose of this article is to examine the meaning and implications of e-learning and to assist individuals and organizations, whether they be schools or workplaces, with implementing e-learning. The author explains his broad definition of e-learning, discusses pros and cons of e-learning, and elaborates ways to effectively lead e-learning through championing, clear communication and effective project management. The article contains information for leaders in education and training—instructional designers, developers, consultants, instructors and administrators.*

Introduction

As we close the door on the 20th century and uncork the millennium we have entered the e-decade. The worldwide Web has given us e-commerce. A new way to sell services, products—anything. The Web and the Net have also increased opportunities to communicate with a large number of people, quickly and cheaply. There are plenty of e-opportunities—all using new technology to grab a larger market share. Maybe even to produce and distribute goods and services more effectively and efficiently. We can hope!

Hurdles to eLearning that must be overcome!

- Quality and intensity of content
- Availability of content
- Habits, customs, and culture
- Technology delivery -- bandwidth, etc.
- Lack of digital collaboration models
- Research gap

Eight issues with e-learning

All is not rosy on the e-learning front. There are challenges, issues—or optimists might say, opportunities—to address. Issues associated with the use of e-learning are as follows.

1. Students may be required to purchase or rent new computer equipment.
2. Technical difficulties or operator error may hamper students and instructors.
3. Students and instructors may have gaps in their computer knowledge in such areas as Windows, so they will require training in computer basics before they can start the online learning training.
4. Using telephones lines and Internet service providers to access Internet services, when required, leads to high user fees in many parts of the world.
5. Initial costs of developing courses may be considerable, depending on the approach taken.
6. Instructors may need to become familiar with electronic text books; Internet-based

research material, copyright, and other e-learning related topics.
7. Internet bandwidth may not be robust enough to support the desired level of multimedia.
8. People working in the e-learning field at an individual location may be pioneers and not have the support of a network of more experienced colleagues.

Our quick review of two baker's dozen plus pros and eight cons tends to underscore the diversity of e-learning. The challenge one faces as an e-learning leader is to reap the benefits and avoid the pitfalls. What can a leader do to achieve success with e-learning? One of the first steps is to become an effective champion.

Summary

Implementing e-learning is not for the faint of heart. It can be challenging. You could experience setbacks, even failure. To succeed you need to understand the up and down side of e-learning. You need to address the weaknesses—especially the perceptions of weaknesses. Successful champions of e-learning are effective communicators. They explain new words clearly, concretely, in terms that their listeners understand. The essence of championing is clear communication. Decide what you need to say, to whom and how. Plan what you are going to say and follow through on your plan. Effective champions anticipate questions before they are asked, find the answers and deliver them in a convincing manner. Tips, tactics, strategies play a pivotal role in the successful implementation of an e-learning program. Plan the start of the project, concentrate on communicating, manage carefully, identify risks and address them, and most of all lead—inspire the people around you with your support for the e-learning project and your reasoned enthusiasm.

Abstract: This research paper attempts conceptually to describe modularity (granularity) of learning content, reusable learning objects and atoms, and reusable information atoms. The premise is that later on those conceptual modular models can be formalized in a form of working models (for example, agent-based models) and be used in e-learning(EL), providing increased effectiveness and efficiency of both EL-related instructional design and teaching and learning processes.

Introduction

Modularity (granularity) is the foundation for a design and development of EL courseware. Using this principle, designers of online degree program will be able easy and quickly to assemble various appropriate curriculum from online courses. Course designers can put together a course by quick integration of existing online classes and lessons using various models of learning sequences and activities. Online lessons can be constructed from a library of standardized learning objects and information objects, such as texts, pictures, images, figures, graphics, tables, essays, video clips, sound recordings, advanced animations, etc.

Hierarchy of Learning Content

We will use the following definitions in this paper: An online course is a sequence of learning experiences enabled by a course designer/instructor and pursued by learners. An online course consists of classes, and each class consists of lessons. Each class and /or lesson is a collection of learning objects and learning activities aimed to accomplish one or several of the sub-goals of the online course. In many ways, an online class is a miniature online course requiring its own objectives, welcomes, introductions, assessments, and feedbacks. Based on given definitions, we will use the following hierarchical structures of *learning content*: 1) Curriculum (Degree Program or Training Program), 2) Courses, 3) Classes, 4) Lessons or *Reusable Learning Objects* (RLOs), and 5) *Reusable Learning Atoms* (RLAs) and *Reusable Information Atoms* (RIAs), and *learning process*: 1) *Learning Sequences* (LSs), 2) *Learning Activities* (LAs), and 3) *Learning Actions.*

Reusable Learning Objects, Atoms, and Information Atoms

RLO's Definition to Be Used In this work, we will use the following working definition of *reusable learning object*: " RLO is any digital resource that can be reused to support Web-based learning". This definition includes anything that can be delivered across the network on demand, be it large or small. Examples of RLOs may include live or prerecorded video or audio, pieces of text, animations, graphics, web-based applications, web pages, and other pieces that are aimed to deliver complete experiences, such as a lesson.

RLO's Structure to Be Used. The proposed RLO's structure is based on the idea that RLO is a collection of Reusable Learning Atoms (RLAs) that are grouped together to teach a common task based on a single learning objective. In order to convert the collection of RLAs into a complete "learning experience" - "a lesson" or RLO, four other Reusable Information Atoms (RIAs), specifically, *Welcome RIA, Overview or Introduction RIA, Summary RIA, and Assessment RIA,* are added to a set of RLAs.

A Reusable Learning Atom is an elementary non-dividable piece of learning that is built upon a single learning objective. Each RLA can be classified as either being a concept, fact, process, or procedure. Each RLA combines three content items, specifically: 1) content items (pieces of learning), 2) practice items (learning activities), and 3) assessment items (tests, quizzes, exams).

A Reusable Information Atom is an elementary non-dividable piece of information that is built upon single information objective. The ***Welcome RIA*** contains only one content item – Greetings. The ***Overview/Introduction*** RIA may contain up to seven different content items, such as: 1) Overview, 2) Introduction, 3) Importance, 4) Objectives, 5) Prerequisites, 6) Scenario, and 7) Outline. The ***Summary RIA*** may contain several content items such as 1) Review, 2) Next Steps, and 3) References/Links/ Additional Knowledge Resources. The ***Assessment RIA*** serves two functions, specifically: 1) *pretest:* tests learners initial knowledge, determines gaps in knowledge and skills prior taking the "lesson", and indicates which RLAs fill those gaps; and 2) *posttest:* ensures the learner has achieved mastery on all objectives for a given "lesson"; determines gaps in knowledge and skills after taking the "lesson" and indicates which RLAs learners should review.

Examples of RLAs and RIAs. Examples of developed types of RLAs and RIAs are given in Table 1.

Table 1.

Type of RLAs	RLA's Description/Function	Type of RIAs	RIA's Description/Function
Knowledge Resources	Provide pointers and hyperlinks to information on the Internet the learner may need before, during and/or after taking the lesson.	Welcome	Greets the learner, tells what the online lesson is about, and makes clear why the learner should take it.
Featured Example, Fact, Concept or Statement	Presents a Web-based description of a single example or case study along with commentary about it (a picture, an image, a concept, a principle, a statement, an event, a phenomenon, a system, etc.).	Overview	Provides hyperlinked general information about RLO's goal, objectives, list of topics, learning procedures/functions/methods to be used, Web-based knowledge resources, and anticipated outcomes.
Code Sample	Demonstrates a self-contained self-executable hyperlinked fragment of a programming or scripting language that can be executed via the Internet (for example, using a sharing application).	Introduction	Establishes the subject and characteristics of the online lesson and prepares the learner to begin the Web-based learning activities.
Event Playback	Lets learners review a previously recorded live event in online mode (for example, video lecture using streaming video and audio technologies, chat session, bulletin board, etc.).	Summary or Conclusion	Recaps the important ideas of the entire online lesson.
Procedure	Provides clear instructions on how to do or execute a given fragment, task, code, etc.	Assessment	A collection of online assessment items.
Feedback	Invites learners to evaluate the effectiveness of the online lesson and to suggest improvements using online evaluation tools.		

RLO's Metadata. In order to compose automatically and dynamically various specific RLOs from a database of RLAs and RLOs, or, more generally, generate a personalized learning sequence of RLOs, the Learning Management System (LMS) must have access to a database with instructional design information to support the decision-making process on "sequencing" the RLOs. As a result, each RLO must be tagged with *metadata* – data about data - that further describes its attributes, functions and associated objects. Usually, metadata include RLO's 1) title, 2) level objective, 3) major topic area, 4) learning objectives, 5) name of designer, 6) name of knowledge source, 7) date of creation, publication date, expiration date, 8) used language (either natural or programming), 9) list of prerequisites, 10) needed technical platform or equipment, etc.

However, in order to increase the reusability of a RLO and make it more efficient and effective, more fundamental RLO's characteristics should be used, for example, 1) ***number of RLAs combined*** – describes the number of individual learning elements (such as video clips, images, etc.) combined in order to make the RLO; 2) ***type of RLAs contained*** – describes the types of RLAs that may be combined to form a RLO; 3) ***reusability of constituent RLAs*** – describes whether or not a RLO's constituent RLAs may be individually accessed and reused in new learning contexts; 4) ***common function*** – describes the manner in which the RLO is generally used; 5) ***external dependence*** – describes whether the RLO needs external information (such as location on the network or Internet) about RLOs other than itself; 6) ***algorithms and procedures*** – describes algorithms and procedures within the RLO; 7) ***contextual reuse*** – describes the number of different learning contexts in which the RLO might be used, that is, the RLO's potential for reuse in different content areas.

Summary of advantages of RLO strategy in e-Learning. In summary, the main advantages of RLO approach to EL include but are not limited to 1) flexibility in RLO's utilization, 2) ease of content updates and searches, 3) adaptation and customization, 4) interoperability, 5) facilitation of a) competency-based, 2) customized, and 3) personalized learning, 6) content management, and 7) increased value of learning content.

National Science Foundation Project on e-Learning in Information Technology

Dr. Vladimir Uskov
Department of Computer Science and Information Systems
Bradley University
United States
Uskov@bradley.edu

Abstract: While the growth in employment of all occupations in the U.S. Information Technology (IT) industry between 1996-2006 is projected at 88.25%, the growth of college/university IT and Computer Science (CS) faculty is only projected at 18.3%. These findings motivated faculty of several U.S. educational institutions to propose the National Science Foundation (NSF) project that is aimed on a design a development of several IT and Computer Science (CS) online degree programs (on both, Associate of Applied Science Degree and Bachelor of Science Degree levels) in the US colleges and universities.

Introduction

Forecasters say that the average worker of the future will have six or seven different careers. Each requires the re-education of a worker who must take new courses and develop new skills, attitudes, and values. Overall, it is estimated that by the end of year 2003, there will be 25 million new learners in the U.S. These learners are more mature and constrained by time and place. Lifelong learners – mature working adults who require continuing education – already comprise 44% of the U.S. student population. On the other hand, traditional undergraduates, those 18- to 22-years-old, attending full time and living in college housing, account for less than 25 percent of all students in U.S. institutions of higher education.

Project Goals and Objectives

Goals. The proposed NSF project on Course, Curriculum and Lab Improvement and Educational Material Development (NSF CCLI-EMD Project) has two goals: 1) accelerating the rate of graduation of Information Engineering Technology students through the active use of innovative online educational materials (OEM) and teaching and learning technology other than Classroom-Based Training (CBT), namely e-learning (EL), and 2) expanding the impact of IT education on various groups of population such as traditional high schools/college/university students and non-traditional students and learners at centers of distance learning, weekend schools, summer institutes, adult vocational centers, career development centers, etc.

Objectives. Given the broad goal of this project, the specific aims of this NSF project are the following ones:

1) Develop online educational materials for twelve (12) IT undergraduate courses, provide wide "beta"-testing of developed OEM, and organize and store IT OEM in form of "IT Courseware Cube".
2) Use actively innovative cost-effective and time-effective Web-based learning and teaching technologies, and "*active learning*" paradigm of education that are ideally match goals and objectives of IT and CS online education of a broad range oftraditional and non-traditional groups of students and learners.
3) Design and develop a specialized "Online IT Courseware" Web server and Web page (available 24/7/365) that will store the developed "Online IT/CS Courseware" Cube of undergraduate OEM and disseminate project-related information nationwide and worldwide.
4) Create a solid foundation for at least two Associate of Applied Science (AAS) and one Bachelor of Science (BS) online degree programs in IT and CS areas.
5) Produce OEM of high quality by using a variety of effective evaluation procedures. Provide various forms of formative and summative discussion and evaluation of all project activities and products.
6) Disseminate project products nationwide by means of various aggressive dissemination procedures with special attention to free distribution of project products to a) historically black and Hispanic educational institutions, b) Tech Prep Consortia in all 50 states, and c) K-16 institutions in rural areas of the U.S.
7) Provide constant active training of faculty and teachers focused on design, development and implementation of OEM, the Web-based innovative teaching and learning technologies and techniques, and state-of-the-art Web-based instructional (WBI) tools.
8) Provide sustainability of project activities by self-sustained distribution of project products by means of 1) production and commercial distribution of CD ROMs with IT OEM, and 2) pre-paid services of the project dedicated Web server.

Project Targeted Audience

Project products are primarily aimed at various groups on students and life-long mature learners in the United States, especially individuals such as:

1) Students of traditional K-16 institutions who find the online learning a convenience.
2) Adult learners who travel a great deal, or have strong commitments for family and/or businesses, and therefore cannot attend weekly on-campus classes,
3) Students who must transfer to another city/state before completing their degree.
4) Adult learners far from U.S. traditional educational institutions.
5) Students in rural areas of the U.S.
6) Disabled students who have no opportunity to attend classes and lab sessions at colleges/universities.
7) Potential international students with Internet connectivity anywhere in the world that are willing to take online courses at US K-16 institutions with no visits or minimal numbers of visits to the U.S.

Project Expected Outcomes

The primary outcomes of the proposed project are expected to be:

1) A set of CD-ROMs that will contain OEM for twelve (12)I ET/CS undergraduate courses.
2) Project's "Online IT Courseware" Cube, project's Web server and Web page.
3) Three (at least) pilot online undergraduate IT/CS programs in participating institutions; several other colleges – project partners, are expected to start their activities on establishment of their own online programs in IT by completion of this project or even before.
4) Project-related articles, papers, presentations, surveys, databases of student FAQ, and evaluation/testing materials.
5) A new mentality of IT faculty nationwide (*"Yes, we can successfully use not only traditional classroom-based IT teaching but also Web-based teaching, and, moreover, various combinations of these two modes in IT teaching"*).
6) A new mentality of IT students and adult learners (*"Yes, we can successfully use a mode of IT education that is the most convenient for me and my family, including CBT, EL, and various combinations of CBT+EL modes of education."*).
7) A designed, developed, and tested "easy-to-replicate" nationwide model of the developed OEM for online undergraduate education in IT.

Particularly, the following undergraduate IT online are planned to be developed.
Online educational materials for **"Software Development and Programming"** IT track:
   1. Web-Based Software Engineering
   2. C++ and C# programming languages
   3. Visual Basic.Net

Online educational materials for **"Networking Systems"** IT track:
   1. Fundamentals of LAN: Hands-on Approach
   2. Fundamentals of WAN: Hands-on Approach
   3. Network Administration

Online educational materials for **"Interactive Multimedia"** IT track:
   1. Web-Based Professional Publications and Presentations
   2. Multimedia Production
   3. Advanced Graphic Design

Online educational materials for **"Information Systems"** IT track:
   1. MS Word, MS, Excel, MS Access applications.: Web-based document and application sharing
   2. Databases and DB Management Systems
   3. Information Systems Analysis and Design

Project Evaluation Procedures

Various formative and summative evaluations will be conducted to assure the quality of project activities and outcomes. Different types of the evaluators will use qualitative and quantitative measures including a) questionnaires, b) interviews, c) observations, d) focus groups, e) instructor and student work samples, f) review of instructor journals, and g) instructor and student assessments. Specific evaluation techniques will include evaluations by students and internal and external experts, peer evaluations by participants at professional meetings, teachers and faculty, attendees of faculty development workshops, and professional journal reviewers.

Engaging Students in Web-Based Self-Development

Abstract: Nutrition and wellness is fundamental to a healthy life. Fostering the importance of nutrition and wellness across the time and space distance of web-based learning environments can be a challenge. Using the Attention, Relevance, Confidence, Satisfaction ARCS model of Instructional Design, we have developed and offered a course that has received great reviews from the students. The ID model and its implementation are described in this paper.

Introduction

Nutrition and wellness is fundamental to a healthy life and requires very active engagement of learners whether they are in a traditional classroom or a web-based distance learning environment. The course presentation, communication, and assessment techniques available in web-based learning environments adds some challenges but also provides new opportunities to engage learners in this very important learning activity. This paper presents a course to introduce reflection of one's lifestyle and and the implementation of healthy alternative behaviors by using the Attention, Relevance, Confidence, Satisfaction (ARCS) model (Keller, 1983) of instructional design. We begin with a brief description of the ARCS model and continue with example modules applying the model. We conclude with a summary of experiences from the course instructor.

ARCS

ARCS was an instructional design model that is based on a theory of motivation and instruction developed by Keller, 1983. The model emphasizes the interest and relevance of the learning to the learner and emphasizes the confidence gained from being successful at completing a task. Each of these elements is described in detail.

- Attention is accomplished by arousing the curiosity of the learners and maintaining their attention throughout the learning experience. This can be implemented using sensory stimuli, inquiry arousal (thought provoking questions), and variability (varying the activities and presentation modes). Examples include presenting learners with some advertisement that overstates its claims of success to arouse their curiosity, a comparison of calories consumed to calories needed and analyzing their carbohydrate intake.
- Relevance to the learner is fundamental to the learning so that they understand and believe in the merits of the learning for themselves. Examples include the development of activities that require the student to take their pulse after activity and observe the changes.
- Confidence can be gained by the learner understanding the requirements of the learning environment and being able to see that they can be successful. This expectancy for success is implemented by setting goals, and providing feedback. Examples include giving students a schedule of activities and time to complete their lessons.
- Satisfaction in the learning is crucial to the long term use of the learned information. This is described as the learner's intrinsic motivation and response to extrinsic awards "(Mory, 1996). Examples are giving the students rewards in grades for reflecting on their eating habits,.reading food labels, anc calculating protein needs.

In summary, the ARCS model is designed to address the issues that are most relevant to creating a web-based learning environment that engages a learner in reflecting on their lifestyle to improve that quality of life. The next section describes two examples of modules created for a course on nutrition and wellness.

Nutrition and Wellness on the Web Using ARCS

We designed and delivered an introductory nutrition and wellness course on the world-wide-web as a distance learning course. This type of course is a required course for all undergraduates attending a liberal arts public university. The course contained information on lifestyle choices such as nutrition, exercise, substance abuse and many related topics and was offered over a 15 week semester. To design a course that would engage learners at a distance and offer them a long term skill we turned to the ARCS model to frame each module. The course requirements included:

- Completion of orientation to learning including checks on necessary hardware and software as well as concept mapping techniques.
- Completion of 12 modules built around a case/problem that the student had to either solve, reflect or assess.
- Readings from the textbook as well as other references.
- Assessment of learning using self-help quizzes.
- Maintenance of an on-going wellness journal (using a private bulletin board which was only viewable by the instructor and student).
- Posting of reviews and/or critiques to the public bulletin board.

The following section describes two of the modules within the ARCS framework to illustrate how the model was implemented.

Nutritional Supplements

To gain the *attention* of the learners advertisements that made outrageous claims on nutrition and weight loss were scanned and placed within the case study(course content). These were *relevant* to the learner because they were part of the daily life of any person reading the newspaper or watching TV. The students gained *confidence* in reviewing the advertisement by following a prescribed evaluation sheet that they completed for review by the professor. After completing their pre-defined evaluation sheet (which asked questions like the source of the advertisement, the research quoted in it, identifying the specific claims and fine print exclusions) the learners selected an advertisement (Remove they ahd seen?) to review using the same guidelines. These product reviews were then posted on the bulletin board of the course and discussed/shared by the students. The students gained *satisfaction* in this module through the grade they received, and the feedback from their peers and professor.

.

Carbohydrate Intake

Each student maintained a Wellness Journal of their daily eating habits, stress levels, physical and mental activities, and general feelings. We gained their attention by referring the students' to review their journal and identify their carbohydrate intake and giving them guidance on how to measure portions. Since this is part of their daily eating routine the relevance was quite obvious. They gained confidence by reflecting on the food choices they were making and identifying alternatives that were assessed by the professor. The satisfaction in this module was very intrinsic with the student realizing how much control they had over their **dietary** habits.

Reflections of the Professor

As the course evolved from the conception to the design and delivery there were many experiences that are important to note. Four of them are described here. First, preparation time for the design and delivery of the course was significant and took about 5 months of full-time effort to create the course. During the delivery there were daily journal entries to read and grade as well as evaluating the submissions and postings to the bulletin board. Second, comparing this experience to classroom teaching it was clear that students engaged in this course and saw how their choices affected their long-term health and lifestyle. Many students commented on the value of their journal using it to set goals and "contracting with themselves" to modify unhealthy practices. Third, there appeared to be increased participation in this on-line class compared to traditional classroom sections of the same courses. Often times students posted opinions/comments on eachothers findings. Finally, students appeared to be less inhibited about sharing their personal thoughts in this delivery mode compared to the face-to-face classroom environment.

Conclusion

Fostering the importance of nutrition and wellness across the time and space distance of web-based learning environments can be a challenge. Using the Attention, Relevance, Confidence, Satisfaction ARCS model of Instructional Design, we have developed and offered a course that has received great reviews from the students.

A Blended Learning Approach to Business in Manufacturing

Dr. Michael T. Wood, Chief Academic Officer, Walsh College, USA, mwood@walshcollege.edu

Marie D. Lee, Instructional Designer, Greenfield Coalition, USA, leem@focushope.edu

Abstract: The Internet is fast becoming a source for learning and educational materials, however, the face-to-face benefits of classroom interaction cannot be ignored. By bringing real world situations into the classroom and constructing activities for students to complete with their peers and a set of resources, higher education can respond to the challenges of industry to create skilled and able workers who can communicate and problem solve on the job. An example of this blended classroom experience is a course developed by the Greenfield Coalition (GC) and Walsh College entitled The Manufacturing Organization and Its Environment (MOE).

Blended Classrooms

From our experiences as students and instructors, we know that listening to hours of lectures sitting in a classroom after a long day's work (or other classes) is not ideal for learning. We have also seen the Internet, as a classroom, fall short in supporting the needs of the learner. However, by integrating web-based learning with teacher guidance and hands-on experiential learning, a better learning environment is created. Blended delivery modes produce a pedagogy that accommodates diverse learning styles and capabilities. The world-wide web (WWW) provides the extended learning base for instructional materials, resources, and some activities, the classroom provides face-to-face interaction and peer learning, while hands-on experimentation allows students to directly apply and practice theory and methods in a safe and supervised environment.

Manufacturing Organization and Its Environment Development

A new example of this hybrid blended learning approach is offered in a one-credit course for engineering and engineering technology degree programs called The Manufacturing Organization and Its Environment (MOE). The course is being offered as a foundation for further study in the business aspects of the engineering profession in manufacturing industry. It is part of the Greenfield Coalition (GC) Engineering and Engineering Technology curricula. GC is funded by the National Science Foundation (NSF) and consists of university and industry partners, the Society of Manufacturing Engineers, and Focus:HOPE. The course, developed by Walsh College and GC, incorporates learning via the WWW, classroom sessions, and a common platform of hands-on, experiential learning that pervades all three modules of the course.

GC at Focus:HOPE is charged by the NSF to revolutionize engineering education by using a blended learning approach and by bringing real-world engineering problems into the classroom. The MOE course blends delivery approaches and is designed, as all GC courses, using Gagne's nine external events of instruction. It will first be taught at Focus:HOPE's Center for Advanced Technology (CAT), in Detroit, Michigan. The students, called "candidates," work an eight-hour day in the factory, which is a tier-one supplier to the automotive industry. After work, they spend 2-4 additional hours in the classroom as they work toward associate or bachelor degrees offered by one of the GC's partner universities. The curriculum is designed to take advantage of opportunities available on the shop floor and integrate them with course concepts and activities. Learning activities are reality-based, and often directly related to the day-to-day operations of the manufacturing facility. Work and study opportunities are linked and allow the candidate to learn in class, at work, online and with peers and mentors.

ADVANTIG Simulation

The common hands-on learning platform for the course is comprised of a manufacturing business role-play simulation. The simulation, called the Advanced Manufacturing Technology Implementation Game (ADVANTIG), is used to help participants learn first-hand how organizations work, and how the components of organization, people and technologies interact. The role-play is threaded through three interrelated modules on: manufacturing organization functions and processes, technology in the organization, and trends in manufacturing and business. Participants preview basic knowledge content via the web, come together and "play" two years of company operation, and learn, with the facilitation of an instructor, skills to improve their mock organization. Between physical-meeting sessions, participants receive new information to study and prepare by way of the Internet.

Participants see how the simulation and a typical year operate, then they do it. A full year is equal to 60 or 40 minutes in the classroom. After each "year," they have time for a retreat and related knowledge-building instruction and discussion. Modules include: relations with suppliers and customers; how to value and plan for technology acquisitions; and how to build communication skills to understand and affect others in the organization. The simulation platform allows for "scenario-updating" each year, so new considerations can be introduced as the learners become more proficient.

ADVANTIG Advantage

The online components of the course allow students and instructors to go to specific learning activities, as this format does not dictate linear presentation or navigation. Instructors can provide dynamic links to external resources to assist study and in-class activities. Materials are made available for work or home study via the course web site. Peer learning opportunities occur in chat rooms for synchronous dialog, or via asynchronous threaded online discussions. Electronic peer and mentor notes support activities and provide guidance as students face challenges.

This blended learning experience allows us to adapt the pedagogy to the learning styles, preferences, and capabilities of the learner, without sacrificing faculty-driven quality educational content and assessment. Educational approaches include:

- Collaborative learning -- participants work in small teams and use peer and mentor learning notes;
- Active learning -- candidates engage in role plays, discussion exercises, and hands-on production work;
- Reality-based learning -- participants use simulations and cases drawn from real-world business practice;
- Flexible learning time -- through the Internet, participants utilize the learning material anytime, anywhere;
- Learner-centered focus -- instructors act as guides and mentors, using the model of "guide by the side."

Responding to Education Challenges

With this blended approach to engineering and business education, it is important to ensure common, consistent, high quality throughout each of the components of learning and methods of delivery. Rather than building a multidisciplinary program based on discrete courses from several academic departments, this approach involves designing multidisciplinary courses that thread two disciplines together in integrated units of learning. Thus, the whole learning experience can be truly greater than the sum of its parts. With the transferability afforded by having the learning materials on the Internet, in stand-alone modules, blended e-learning in engineering and business can eventually be available to a wide audience of 21st century learners.

Acknowledgement

The Greenfield Coalition is partially supported by a Grant EEC-9630951 under the Engineering Education Coalitions Program at the National Science Foundation. Focus:HOPE, our industry and academic partners have contributed valuable resources to support the development of Greenfield.

Seeing is Believing! Can Students Learn Culture Using Distance Education?

Jack Fei Yang, MBA, Ed.D (ABD)
The University of South Dakota
fyang@usd.edu

Ching-Mei Hsiao, MBA, Ed.D (ABD)
The University of South Dakota
chsiao@usd.edu

Abstract Can students learn culture using distance education? Emerging technologies have potential to support the use of video to provide live and virtual interaction among diverse cultures. This paper will demonstrate how distance-learning resources in South Dakota can create interactive environments to further East/West cultural understanding. Cultural study through distance education can allow students to experience culture first hand, rather than reading about culture as defined by a textbook. A demonstration will focus on how core values of different cultures can be shown interactively through distance learning.

Introduction

The students of a global society confront daily the question of how the world does things. Many people want to understand cultural differences and similarities and to assimilate new best social behaviors, values, and practices that will make up the concept of "global culture." What are the elements of "culture"? Peterson (1979) stated that culture comprises four elements: norms, values, beliefs, and expressive symbols. "The popular definition of culture has come to refer to the shared values, attitudes, beliefs, behaviors, and language use within a social group" (Talmadge, 1999, p7).

Cultures are a kind of natural system of customs and behaviors that are passed from different generations, races, genders, ages, or groups to the next. The rules for a culture could consist of elements such as language, religion, education, politics, recreation, and family systems that a group of people share together. More complex cultural issues may be related to social behaviors in matters of more difficult matters of sexuality, morality, spirituality, social control, and the search for meaning in life. Among this wide set of topics, how can emerging distance learning resources be a catalyst for learning? How can these sometimes subtle and complex factors of culture be best learned through distance education?

Distance Learning as an Interactive Medium for Global Students of Culture

Chaney and Martin (2000) mentioned culture is learned through perception; the traditional textbook with literature approach was difficult to provide an active-learning and experiential learning environment to students. Language is the most representative element in any culture, but language is not equal to culture, and knowing only language but not culture is dangerous; it causes misunderstandings. The activities to teaching culture could includes all kind of culture topics such as, capsule, cultural consciousness-raising, cultural islands, celebrating festivals, kinesics and body language. The purpose for these activates are to help students to feel smell, touch, and see the culture difference.

Oxford (1994) pointed out in order to teach culture to students, the teaching should be based on a "cultural texture" concept, which includes three different parameters: information sources, activity-types, and selling-points. Current technology provides diverse available information sources; it includes video, CDs, TV, and the Internet. Technology developments can improve teaching resources and create a multimedia-learning environment. Appropriate teaching technology resources can give students a chance to experience interactive learning environments. Current distance teaching methods include correspondence courses, prerecorded media, two-way audio, two-way audio with graphics, one-way live video, two-way audio with one-way video, two-way audio/video, and desktop two-way audio/video (Simonson, Smaldino, Albright & Zvacek 2000). In this paper, researchers will focus on the applications of some of these methods in South Dakota distance learning systems in which distance education can be used to introduce cultural differences and similarities.

South Dakota Distance Learning System Introduction

The Dakota Digital Network (DDN) in South Dakota is a two way audio and video medium; the DDN connections provide Internet access and videoconferencing over a statewide intranet. The DDN connections include about 180 South Dakota K-12 school districts and six South Dakota public universities. Another local area network in South Dakota is the Southeast Interactive Long Distance Learning (SILDL) system. It is also a two way audio and video medium. The SILDL connects to educational institutions pre-K through post secondary and university levels, but in a region of the southeastern part of the state. The SILDL system allows four different classes to operate at the same time even if they are in different locations within a 200-mile radius.

The practical functions in WebCT include chat rooms, message boards, and e-mail to allow instructors to communication actively with students either asynchronously or synchronously. In South Dakota at the university and k-12 school levels, the WebCT product has been used in digital statewide networks to support distance-learning options. The Internet is a most convenient and common learning resource for distance-learning systems, it provide more interaction and more first-hand resources for students. The practical distance teaching techniques with culture will be demonstrated during the presentation.

Conclusion

Distance teaching technologies provide many new methods for creating real and virtual experiences for students. It is possible for emerging multi-media resources to allow a "seeing is believing" environment. Visual and real contact among people of different cultures can contribute to the further development of friendships, safe higher-level learning environments, and development of a global culture. Educational research has long shown that active learning, visual presentation, problem solving, and engagement in learning can be more effective than passive learning alternatives. The challenge to future educational leaders is to use the best of educational technology to bring more active learning to the education of students who will lead the development of the new global society. In a learning environment of trust among people, there are many avenues in which interactive media may encourage discourse among people. Distance education is a potentially powerful concept in this decade. As technological change continues to bring cultures of the world into interaction, there is an increasing need to synthesize norms, values, and social behaviors into a synthesized global society gestalt.

International issues in using web technologies in higher education.

The purpose of this paper is to indicate the role of international issues in using web technologies in higher education. The main focus is on common uses of web technologies in developing countries and related issues such as accessibility, high price of hardware, software, lack of the knowledge of web technologies, computer phobia and computer illiteracy of students in the higher education of these countries. The second focus of this paper is to identify the role of cultural factors such as language, traditional culture and stereotypical impressions affecting the use of web technologies among students in the universities of developing countries. The educational systems' goals in the primary and secondary schools and the schools' culture and curriculum are also important in the success of using web technologies in the higher education of developing countries. Based upon the results of this study, recommendations will be made for success implementation of web technologies.

Participants were samples of students and professors from different majors of the educational department of Isfahan University. Both graduate and undergraduate students were included in this research. Semi-structured Interviews, questionnaires, observations and archive data were the most important data gathering instruments.

The results of this research (2001-2002) confirm the results of other researchers from various universities of Iran and other developing countries. The results indicate that students in both levels have used a few capabilities of the web technologies. The most important use of web technologies was for doing dissertation and research projects. No courses were presented by web technologies. Both groups were positive toward using computers and they believed that web technologies are useful for communicating and acquiring new information. Access to hardware and software, computer illiteracy, lack of research skills and web technologies knowledge were reported by the participants. Cultural issues related to social attitudes and beliefs were other expressed problems. The results of this study indicate that for using web technologies in developing countries, some consideration in different areas should be taken. These considerations would be discussed in this paper.

Creating Computerized Multimedia Chinese Language Lessons with the KEY 4.0 Timed Reading Module

Sheri Senquan Zhang
Department of Education, University of Ottawa, Canada
senquanzhang@hotmail.com

Abstract: The KEY software from the Canadian developer CJKWARE.COM is a word processing, authoring, learning and teaching system for the Chinese language (Japanese & Korean included). In addition to its existing E-Learn and lesson-authoring features, i.e. (a) automatic generation of Pinyin-with-tone-marks transcription for Chinese-character text, (b) Tool Tip lookup through the Chinese/English dictionary and (c) automatic glossary-building, the new (August 2002) version KEY 4.0 for both PC Windows and Macintosh OS 9.1 / OS X introduces a new E-Learn module for enhancing reading comprehension: Timed Reading. Through the built-in Chinese Text To Speech (TTS) system, the Timed Reading module allows the teacher of Chinese to automatically generate annotated interactive multimedia lessons from any Chinese text in electronic format, e.g., text from the Chinese web. It further enables the learner of Chinese to independently run electronic Chinese text as a computerized multimedia Chinese language lesson.

The Basic E-Learn Components of the Software

Besides being a word processing and desktop publishing system for writing Chinese, Japanese and Korean, KEY / MacKEY in its new version 4.0 (August 2002) includes several innovative authoring, teaching and learning features for the Chinese language. The structural E-Learn components that are integrated in the Timed Reading module are:

- The 240,000-word Chinese/English dictionary using the Tool Tip technique: hovering the mouse pointer on a word in the Chinese character text (without clicking) displays the word's Pinyin-with-tone-marks transcription, its English meaning(s), and further reads the word in its Modern Standard Chinese reading, with a natural human voice;
- The "Hanzi with Pinyin" feature: Chinese character text copied & pasted into the KEY edit screen, is supplemented upon learner request with a second parallel line of its Pinyin-with-tone-marks equivalent, with the correct word boundaries of the imported single-character-based text being automatically reconstructed;
- The bidirectional "Simplified / Traditional Chinese conversion" feature: Chinese Text in Traditional Chinese characters can be converted into Simplified characters. More importantly, Simplified Chinese character text can be correctly converted into its Traditional character equivalent, thus solving the Simplified / Traditional multi-mapping problem. (Explanation: During the language reform that took place in the People's Republic of China around the middle of the twentieth century, two, three or even more different complicated "Traditional" characters were consolidated into one "Simplified" character. Therefore, converting a Simplified character text to its Traditional character equivalent involves ambiguities that have to be resolved through a context-sensitive approach.)
- The Text To Speech module, which reads a marked text passage through the computer's audio system in standard Mandarin, with tone sandhi (change of tone depending on the tone of the following syllable) implemented;
- Automatic glossary-building for a given Chinese text: upon teacher / learner request, the Pinyin-with-tones transcription and the English meaning of words specified in a text are extracted from the dictionary and added to the word list in columnar alignment, resulting in a complete vocabulary glossary;
- The ability to create annotations to a Chinese text, even to multi-part grammatical structures; such teacher / student annotations can be hidden and viewed through the Annotation Tool Tip.

The Timed Reading module consolidates all these components, by allowing the teacher / learner to specify which of the features should be active when the KEY software converts a Chinese text into the E-Learn format of an electronic interactive multimedia lesson.

An Electronic Multimedia Chinese Language Lesson

Besides its interactive, dynamic multimedia capabilities, perhaps the greatest plus of an ad-hoc authoring system like KEY is the up-to-date nature of the resulting lessons. While conventional print-, video- and computer-based E-Learn materials may efficiently teach the basics of a foreign language through a fixed set of predefined lessons, language in truly authentic materials acts as a vehicle to deliver the current social and cultural meaning of the target language to the learners. Authentic materials can be used as a mirror of culture (Zhang, 2002), allowing learners to see how new vocabulary develops along with culture change. The world is changing rapidly in the 21st century, and in many ways is growing more transcultural than ever before (Atkinson, 1999). In other words, truly authentic materials reflect the language use, vocabulary and the culture of the target language community *here and now*, not of ten years ago when a particular text book or video course was created. The gap in authentic, up-do-date learning material is filled by an authoring and learning system capable of creating an ad-hoc reading lesson from *today's* newspaper article, which the learner can study *tomorrow*.

The dynamic ad-hoc authoring capabilities of the KEY 4.0 software are beneficial for teachers and students alike. Teachers can edit and annotate a news passage from the Chinese web and pass the lesson on to their students on diskette, or as an E-mail attachment – the students run the lesson on their multimedia computer. Learners at a more advanced level can independently copy & paste a text passage from the Chinese web onto their computer and instantly run it as a lesson with explanations. In more detail, with KEY 4.0 Multimedia learners of Chinese can

a) Select (=highlight) the Chinese web text displayed in their browser, and "Copy" it on the clipboard;
b) "Paste" the text into the KEY screen;
c) Select (=highlight) the text, and from the KEY Format menu choose "Hanzi with Pinyin". This displays a second line with the Pinyin-with-tone-marks equivalent of the Chinese character text. We can see from the word segmentation of the Pinyin transcription that the word boundaries were automatically reconstructed when the text was copied & pasted into KEY;
d) Use "Text To Speech" to listen to highlighted passages;
e) Use the "Dictionary tool tip" to display the meaning(s) of the Chinese words and their Romanization;
f) Check "Read tool tip with Text To Speech" to hear the Mandarin Chinese reading of the words;
g) Convert the Chinese text into a dynamic, interactive multimedia lesson, by pressing the "TR" (Timed Reading) button on the toolbar, and specifying the various "checks" they want included in the lesson;
h) Run the multimedia lesson in interactive mode;
i) Use the Annotation feature to annotate certain words, grammatical particles, multi-part structures etc.; hide the annotations, and retrieve them with the "Annotation Tool Tip".
j) Automatically build a Chinese/English glossary for the Chinese text, by
    - Copying/pasting the text beneath itself, so that it appears on the screen twice;
    - Using "Return" to segment the second copy of the text into words, one at the beginning of each line;
    - Clicking "Convert to Glossary" (Format menu), which automatically provides the pronunciation and the English meaning for each term, arranged in columns.

In summary, the KEY 4.0 Chinese authoring, teaching and learning software

- Enables learners to analyze and comprehend authentic Chinese web text,
- Allows teachers of Chinese to generate a dynamic multimedia lesson from static Chinese text, such as from the Chinese web.

In the contexts of FLA (Foreign Language Acquisition) and SLA (Second Language Acquisition), this Chinese authoring, teaching and learning system shows a way to complement classroom-based instruction and print-based teaching material with corollary software-based teaching- and learning techniques. Enabling the various features in the checkboxes of the Reading Timer panel allows the learner to thoroughly analyze a Chinese text passage, within the self-imposed time constraints of the Reading Timer. Word boundaries, pronunciation, Pinyin transcription and the English meaning are taught in a dynamic and integrated multimedia lesson. The developer's website is http://www.cjkware.com

Mathematics Education Markup Language

Paul S. Wang* Yi Zhou Xiao Zou
Institute for Computational Mathematics
Kent State University
Kent, Ohio 44242-0001, USA

August 18, 2002

Abstract: On-going design of *Mathematics Education Markup Language* (MeML) is presented. MeML is an XML-based language and the key component of Web-based Mathematics Education framework (WME) under investigation. MeML enables authoring of systematic and interoperable mathematics education pages that may contain *active parts* for various mathematics and educational purposes such as example generation, answer validation, difficulty diagnosis, exploration, and plotting of curves and surfaces. A server-side MeML interpreter performs the dynamic computations in an MeML page and generates a regular Web page for delivery to regular Web browsers.

1 Introduction

Web-based learning has anywhere-anytime availability and many distinct advantages. Currently, there are several problems on authoring Web pages for mathematics education: technique obstacles, computation difficulty, time consumption, lack of five ilities (modularity, reusability, exchangeability, adaptability, and machine-understandability). Recent advances in *Internet Accessible Mathematical Computation* (IAMC) and MathML [4] make delivering mathematics education over Web really possible. There are also many Web Sites providing mathematics tools [1]. Efforts have been made by Institute for Computational Mathematics (ICM/Kent) to build a *distributed IAMC framework*[3].

We propose MeML aiming to systematically solve the existing problems for Web-based mathematics education. MeML is a pivotal component in *Web-based Mathematics Education* (WME) [6] framework being investigated by our research group at ICM/Kent.

2 Context of MeML

MeML functions within the WME framework that aims to support easy development and deployment of *mathematics educational content* and *mathematical & other support programming* for the Web. Content pages and support programs can be developed independently and interoperable from anywhere over Web. Figure 1 shows the WME framework architecture.

3 Goals Of MeML

MeML is designed to facilitate authoring, storing, processing, and exchanging learning materials for mathematics education over Web. MeML can represent mathematics domain knowledge, describe the actions during mathematics education (such as exercising, assessing, and etc), and do the computations for mathematics education at high school or college level through back-end computing engines. MeML is designed with following merits:

- *Easiness:* MeML pages can be authored with any text editors or MeML authoring tools without knowledge of HTML, Web programming and etc., which overcomes the technical obstacles for them.

---

* Work reported herein has been supported in part by the National Science Foundation under Grant CCR-0201772 and in part by the Ohio Board of Regents Computer Science Enhancement Funds.

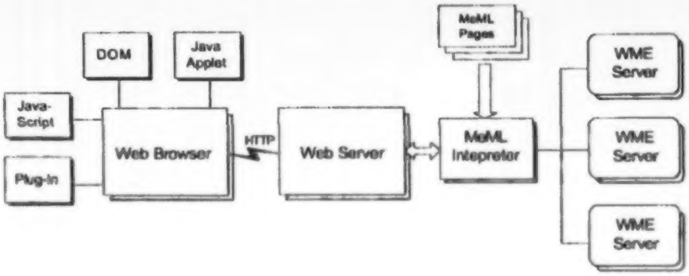

Figure 1: WME Architecture

- *Computation:* MeML provides advanced computation with the MeML back-end support, which dramatically ease authoring tasks.
- *Efficiency:* MeML Authors only need to define *what to be taught in what ways*. How to obtain mathematics teaching stuff is internally done by MeML back-end supports.
- *Modularity & Reusability & Exchangeability:* With MeML structure elements, the content of web pages can be organized into well-defined modules, which provides reusability and exchangeability and makes full use of mathematics education resources over Web.

4 Design of MeML

Mathematics Education Markup Language (MeML)[7] can embed MathML in it and can be embedded in HTML pages. An MeML page can have both fixed and dynamically generated contents. MeML interpreter controls content generation and accesses WME servers for certain requested information. One MeML page can specify all necessary interactions for Web-based Learning. All MeML elements are encapsulated in the `<meml/>` element. MeML has five types of elements: *content elements*, *education elements*, *structure elements*, and *computation elements*.

5 Conclusion and Future Work

MeML enables authoring Web pages for mathematics education easily and efficiently. It shelters authors from the technical complexity. Our solution is implemented on Windows 98/2000/xp with Apache Http server 1.34, and MathLink/Mathematica 4.1. In the future, we will focus on refining the draft of MeML specification, and implementing a full version of MeML context - WME framework.

HAPPENINGS: A FORAY INTO ELEARNING

The purpose of this poster session is to provide an overview of Happenings, a type of e-Learning and to provide a walk-through of three Happenings. The poster will be divided into two segments. The first segment, titled, "About Happenings" provides an overview. The second segment, titled, "Examples of Happenings" will demonstrate three Happenings being developed by Education Development Center, Inc. (EDC).

About Happenings

This component of the poster session will present and describe our definition of a Happening, its purpose, intended audiences, and design principles.

A Happening is an online learning event for educators. The purpose is for classroom teachers, specialists, and administrators to deepen and expand their knowledge on a particular topic. A Happening is similar to an online workshop in that it seeks to promote professional development through a series of interactive activities. But it is characteristically more playful and less structured. Therefore, it serves as an effective foray into e-Learning for teachers who are interested in pursuing new modes of learning, but whom may be new to online learning.

In designing our Happenings, we adhere to the following set of design principles:

- Each Happening focuses on a well-defined topic.
- Happenings are short in duration, often lasting between two and four weeks.
- There is no formal registration process.
- The navigation is easy to understand and intuitive, requiring few directions.
- For some Happenings, participants can choose multiple entry points; a structured order sequence is not important.
- The activities are designed to be engaging, drawing on current research and findings about adult learners.
- There is an expectation that participants will try out ideas from the Happening in their classrooms and then report back the results online.
- The Happenings make liberal use of graphics and photographs.
- Video clips are used to enhance online instruction.
- Participants can easily access additional information by following links to other noteworthy web sites.
- Activities are connected to discussion areas that are facilitated by a qualified facilitator.
- A technical moderator is available to answer questions about the web site, navigation, and discussion software before and during the Happening.
- The "Big Ideas" are summarized and added to the web site at the conclusion of the Happening.

Examples of Happenings

We will present Happenings that are being created for as part of the total professional development program for two projects at EDC: the Literacy Matters Project (funded by the Annenberg Foundation) and the LINK US Project (funded by the U.S. Department of Education).

Literacy Matters

The Literacy Matters Professional Development Program seeks to help teachers and reading specialists improve the reading and writing of all students, and especially students who struggle with literacy development. Literacy Matters offers instructional leaders and teachers a coherent set of activities and resources: face-to-face workshops; access to the Literacy Matters web site; an opportunity to participate in a series of Happenings; video conferences conducted in between the Happenings; a teacher sourcebook containing curriculum materials; and guidelines to support implementation at the local level.

The poster session will present the Happening called, "Literature with Inclusive Themes" Help Me! Find What Works for the Middle Grades." The purpose of this Happening is to help teachers locate and effectively use literature that values diversity.

The Happening, mounted on the Literacy Matters web site, invites teachers to participate in interactive activities such as the following.

- *A Teacher's Dilemma*: Through text, audio, video, and photographs we present a common issue related to the theme as a springboard for teacher discussion.

- *Try It!:* Participants are encouraged to download instructional materials, try them out in their classrooms, and report back what happened.

- *Point/Counterpoint:* Participants debate the pros and cons inherent in two different philosophies about teaching and learning.

- *Read and Discuss*: Participants read and discuss selected online journal articles.

- *Kid's Gallery:* Teachers will invite students to publish their compositions, excerpts from journals, poems, essays, and artwork.

BEST COPY AVAILABLE

- *CyberGoodies:* Participants link to theme-related instructional resources cited on the website and discuss how they used them in their classroom.

- *Links Plus:* Participants access an annotated, hyper-linked bibliography of theme-related materials, most of which are free.

- *Analyzing and Evaluating Student Work:* Teachers post students' compositions and develop a protocol for discussing common characteristics.

LINK•US

The LINK•US Project has developed a comprehensive professional development program called, STAR TECH (Supporting Teachers to Achieve Results by Integrating Technology). The goal of the program is to improve the way in which teachers in urban school districts integrate technology tools into the curriculum to benefit all students with diverse needs and abilities, and especially those students who have disabilities. In the STAR TECH model, teachers meet in small school-based teams to carry out a process that links curriculum, instruction, and assessment to the use of technology. During team meetings, teachers and specialists discuss the abilities and needs of diverse students, clarify curriculum, goals, generate powerful instructional activities that embed technology, and plan assessment. To make the link between instruction and assessment as tight as possible, they follow a protocol to look at student work. In addition to this ongoing face-to-face professional development activity, teachers also have access to Happenings.

We will present two of the LINK•US Happenings. These Happenings were created to provide more structure than the Literacy Matters Happening, whereby teachers to follow a guided, multi-week process.

The first Happening, entitled "E-Team," was designed to serve as an introductory Happening. In this Happening teachers do they following:
- Read a classroom-based problem that is reminiscent of the one teachers pose in face-to-face meetings, and then follow links to additional information
- "Vote" for a solution and discuss their reasons for making that choice
- Engage in online conversations.

In the second Happening, called "STAR Quality Classrooms," teachers become members of a virtual team. This Happening was designed to link teachers across numerous urban school districts, giving them a chance to broaden their collaborative work. Online, participants are able to engage in the same process of discussing student work, curriculum, instruction with technology, and assessment as they do when they are face-to-face.

This Happening runs for four weeks, with each week having a different activity as described below. For each activity, teachers select the grade level that is appropriate for them (K-2, 3-5, 6-8).

- *Week 1: Imagine.* Teachers engage in an activity called "Imagine." Teachers are provided with information about a fictitious student and a particular technology tool (e.g., portable keyboard, Inspiration, sticky notes). The teacher is invited to imagine using the tool and post a description of the activity, along with imagined curriculum goals and assessment strategies. After a week of postings, participants can view a chart that synthesizes all of the ideas.

- *Week 2: Looking at Student Work.* This activity replicates the looking at student work process that occurs within the school-based teams. Teachers are introduced to a fictitious student and provided with the highlights of his strengths and needs, provided with the curriculum goals, given a "problem" posed by the classroom teacher. Teachers then study the student work online and make interpretations. They also offer suggestions for strategies.

- *Week 3: Try It!* During this week, participants have access to varied lesson plans that integrate technology. Teachers are encouraged to find a colleague and try out one of the activities. They then report back by explaining their curriculum goals, what they did to implement the activity, assessment strategies, and what they learned about their students' performance.

- *Week 4: Galaxy of Stars.* The last week is the culminating activity. On screen are photos of teachers superimposed on stars to create a "galaxy." Participants can click on any of the teachers who have tried out activities and taken the time to report results. After clicking on the picture, participants can read about the activities the teachers tried. They can send an email with comments and questions.

The poster session will be lead by Judith Zorfass, lead designer of Literacy Matters and LINK•US and Jen Minotti, web designer and technical consultant. Those attending this poster session will have access to information mounted on the poster board and provided in handouts; will be able to try out the Happenings online; and will be able to ask questions and make comments.

The Personalized Courseware Authoring Tool

Yanhua Cao
National Laboratory of Machine Perception and Center for Information Science
Peking University, Beijing 100871, China
Yhcao@cis.pku.edu.cn

Abstract: With the personalized digital service more and more applied in e-commercial, recently, the personalized conception is introduced in the modern distance education. So far, what has been more discussed is to have the platform of the distance education process the personalization, which can deliver an appropriate material to the different learners according to the different learners' behavior, such as accounts of visiting favorite course, frequency of visiting and steps of learning. In this paper, we introduce the personalization into courseware authoring system. The personalized courseware authoring tool is mainly for an instructor to prepare the lessons that can be browsed in a distance learning platform. Using the tool, an instructor can frame the personalized courseware that can provide the special learning material matched to the learner's learning foundation, step, style and impact.

1 Introduction

"Providing special treatment in the form of information and applications matched to a visitor's interests, roles, and needs is known as personalization." With the development of the modern distance education, the personalization in the distance education becomes more and more important. But in the distance education platform, the courseware is "static", i.e. it's invariable at every time when a learner visits the webpage. In our opinion, if a courseware is "dynamic", it can meet the different needs of the different learners. When the learner visits an on-line course in its own styles and steps, the courseware can form the webpage dynamically to fit the learner. We call this dynamic courseware as a personalized courseware. Therefore, we propose a tool that can author the personalized courseware.

The paper contains four sections. In Section 2, we will discuss the personalized thought revealed in courseware authoring tool. In Section 3, we will introduce the structure design of the tool. Finally, the conclusion and the future work will be presented in Section 4.

2 The personalization in the courseware authoring tool

2.1 The personalized teaching pattern

We adopt the multiple-unit model in our authoring tool. The beginning of a course is set according to the individual differences of the different learners, then the best track is chosen according to the learning impact, finally the same academic goal is attained.

2.2 The personalized teaching strategy

We adopt the adaptive diagnostic teaching strategy in our authoring tool. The evaluating system is designed for evaluating the condition of student's knowledge and learning impact before and during the learning progress, to adjust adaptively the teaching strategy via feedback suggestion. Then a series of performance objective is established for the different learners in each learning stage. Finally teaching unit is designed utilizing the different teaching material, medium and learning route according to student's characteristic.

3 The design of the tool

The tool is composed of the four modules: Content-editing, Templet-forming, Learning- strategy, Testing-evaluating. Compared with the conventional courseware producing tool, the following different objects are designed.

- **Instructive object**

The instructive object is a least unit. It is composed of text, hyper text, animation, audio, video and image. It is an independent knowledge point in a teaching material or book. Teaching content is separated into a series of learning object so as to be organized into a flexible course unit.

- **Instructive link**

The instructive link gives the sequence of instructive objects, indicating their correlation and instructive order.

- **Testing object**

The testing object is consisted of testing item and testing value, indicating the degree of obtaining the instructive object and the value of spanning the instructive object.

- **Encapsulation Format**

The encapsulation format defines the present interface and representation form of the instructive object. In the tool, sorts of characteristic templet are offered to be selected.

- **Resource link**

The resource link is the super link to the instructive object's reference information, relevant information and relevant FAQ (Frequency Asking Question).

- **Customer object**
  - The customer mark records the learner's present level of attaining the instructive object, and the sign of spanning the instructive object.
  - The usage range describes the suitable user of instructive object.
  - The time range indicates the maximum and minimum time for learner to obtain the instructive object.

Meanwhile, to match the using of the personalized courseware, the dynamic network service management technology is adopted in the distance education website, so that can dynamically, nonlinearly, stretchable, customized recombine or adjust the network teaching service according to each learner. The instructive courseware is enveloped by XML language, defining the element, attribution, mark, entity and correlation in XML schema, representing the courseware with CSS.

4. Conclusion

Our personalized courseware authoring tool provides a simple and efficient way to edit a courseware that can meet the learner's personal need. In the future, we will perfect our tool and the corresponding tool to build up a whole personalized education system.

Abstract

This paper addresses the importance of assessing and realizing student's needs and expectations while developing a virtual learning environment (VLE). Realizing student's needs in the development of the VLE is one of our key interests out of the pedagogical perspective in the project "Virtual OR/MS" (Vorms). Only if we involve our target group in the design and development process of the learning environment we can ensure that they are going to be satisfied with the product we are developing for them. The thoughtfully defined target group is the basis for developing effective evaluation forms. This paper describes the results of the combination of qualitative and quantitative empirical research and evaluation.

1 Introduction

The project Virtual OR/MS is funded by the BMBF (Federal Ministry of Education and Research) of the German Government. It involves seven German partners from six Universities. The goal of the project supports the four trends as judged by Longworth to be essential in managing the challenges of the 21st century:

1. increased use of educational tools and techniques,
2. greater use of national and international networks,
3. development of co-operative and two-way partnerships, as well as
4. development of learning organizations and individual empowerment

(Longworth 1996).

The close cooperation with the project OR-World (Kassanke 2000, Kassanke 2001), funded by the European Community, enables us to build upon an already existing technological framework. The learning and teaching environment created in OR-World is non-linear and multidimensional allowing cost-effective creation and sharing of materials as well as a personalized mix of contents. Vorms focuses on content generation. Students will be able to visit courses which are based on joint hypermedia environments or explore the hyperspace in a self-study process. Looking upon these goals from a pedagogical point of view, it is very important to design a didactical concept. This concept will integrate the expectations of the target group where possible.

To meet student's expectations in a VLE it is essential to know as much as possible about the target group. In a first step of the realization of our pedagogical goals this was done by the team members of the Vorms project. After outlining for whom the VLE is being developed, the expectations of these persons were evaluated. This was done by conducting a combination of qualitative research, realized as group discussions, and quantitative research, in form of a questionnaire. The evaluation methods, their results, and the conclusions we made for the development of our VLE are the focus of this paper.

2 Target Group

Defining the target group is an essential step in the development of a learning environment (see Euler 1992, p. 85). For the time being Vorms focuses on University students, who specialize in Operations Research (OR). In the future, Vorms also wants to address company employees, who want to extend their knowledge about OR. These two target groups are very homogeneous considering the relevant characteristics for the learning environment, thus it is possible to widen the scope of the target group for the future.

Learners who are interested in the subject OR and have a business background are the target group for Vorms. Their situative, affective and cognitive dispositions can be characterized as follows:

Situative disposition

- Computer-familiarity is rated between high and very high.
- Content-familiarity is rated as low.

Affective disposition

- The acceptance of computer aided instruction is rated as high.
- Learning demands are factual.
- Feedback in the learning process is received as objective, not as personnel feedback.

Cognitive disposition

- An active, intrinsically motivated learning style is assumed.
- The subjective perception is the favorable perceptive faculty.
- Abilities of processing new information are rated as high.

3 Evaluating students expectations

The systematic evaluation was divided into two parts (see Stufflebeam 1985, p. 176; Falk 1995, p. 123). In the first part qualitative, empirical research was done to collect qualitative data. In the second part, the results of the qualitative data were validated, by transferring them into a questionnaire, a quantitative research method, to determine the distribution of the expectations.

3.1 Group Discussion

The group discussion is a qualitative, empirical method and is used to give the interviewees freedom to state what they think, without pressing them into predefined categories (see Kromrey 1998, p. 267; Flick 1996, p. 10). Approximately 120 students were interviewed in groups of about 10 students per group. Techniques such as free associating (see Schnell 1988, p. 391) were used to identify topics of importance to the learners, and other techniques such as focusing (see Koenig 1999, p. 149) were used to explain these topics. After identifying and defining topics of importance, additional key questions were asked, to make out further topics of interest. The results of the group discussion were rated systematically in form of a category system (see Koenig 1999, p.162).

Results of the group discussion

Students expectations regarding VLEs can be grouped into the following categories:

- Installation
- User-orientation / Navigation
- Software-ergonomics
- Content
- Learning Assessment
- Help Functions
- Examples
- Internet Functions.

Installation

If installation is necessary, students expect installation and de-installation to be fast and complete, leaving no debris after de-installation. Students want to be able to decide the installation path themselves, they do not want it to be a default setting. There should be more than one installation version of the program, i.e. a customized version for laptops is rated as important.

User-orientation / Navigation

The main expectation in the category of user-orientation is that the learning environment meets common standards. Students want the navigation to be easy and intuitive to use. Students want to be able to navigate freely to explore the learning environment, as well as being able to use guided tours. They want the possibility to activate a guide, that shows them how the program works. Pages that have been opened before should be marked visited, with the option to clear the mark manually. Many students declare, that they want to be able to use bookmarks, make their own comments on pages or use highlighting pens.

Software-ergonomics

Few students come up with this topic on their own. Once asked by the interviewer many students stated, that the learning environment has to have good software-ergonomics. After inquiring further, the students were not able to describe what they meant with "good", mostly they said they couldn't describe it, they would need to have an example and then they would be able to say this product has good or poor software-ergonomics.

Content

Students expect a VLE to give an overview of all topics covered in the corresponding lecture. Contents of the lecture and the learning environment should be synchronized. One idea to realize this is to offer a guided tour, which is built up in the same structure as the lecture is. The electronic version should extend the contents of the lecture, so if the student is interested in a certain topic, he can get more information to this topic from the learning environment, and he does not have to search in any other information resources. Some students want the VLE to offer complete exam preparation. Several students wanted the VLE to offer different access possibilities to explanations. For example they imagined choosing either textual or mathematical explanations for the exercises. Most students requested the VLE to estimate the time needed to complete a learning sequence.

Learning Assessment

Some kind of learning assessment is requested by almost every learner. Students want the VLE to supply plenty of questions so they can practice very much, not having to repeat the same examples over and over again. They want to choose exercises from a pool of questions with varying difficulty levels. Some students want to choose the difficulty level themselves. Others would prefer for the VLE to keep track of how good they are and ask the next questions according to their skill level. These students would like the VLE to decide in which area they have trouble answering questions correctly, and then ask them questions to these subjects. Several students state that they want some kind of reward for questions they answered correctly. This should not be too time consuming however. Several students proposed integrating a function, which simulates tests. Miscellaneously picking out questions and giving the students only a certain time to answer them – similar to doing a test in class. They are also keen on integrating tests, including their answers, out of the previous semesters into the VLE. It was also proposed to integrate a feature for sending questions to a tutor via email and getting personnel feedback.

Help Functions

Helping functions such as an abbreviation dictionary, an online help, a search function, an English dictionary, a glossary, and an overview of all used symbols are asked for.

Examples

Students want the VLE to offer many examples. They should not only be theoretical ones, but also ones out of real practice. Transfers of theory problems to real life problems should be made. Simulations and animations are also requested by the students to illustrate problems. The speed of animations should be individually settable and an animation must be stoppable at any time. It seems very important to the students to integrate all examples used in the lecture.

Internet Functions

An internet-based learning environment would be favored by some students to enable group work und update functionalities. They would like to be able to learn from anywhere at anytime. Some students proposed implementing discussion databases, but even though they wanted them, they were not sure, if they would use them regularly.

3.2 Questionnaire

The second part of the evaluation uses the questionnaire method to validate the quantitative data collected in the first part. The questionnaire was developed according to the results of the group discussion. The questionnaire was answered by 58 students. 42 male students and 16 female students. This relation of male to female students represents the target group. The gender differences will be pointed out in the evaluation of the questionnaire.

Results of the questionnaire

The results of the questionnaire will be presented in the two categories: Work Independently and Self Assessment. The categories of the group discussion can be divided into two major categories. These are shown below in table 1.

Work Independently	Self Assessment
• Installation	• Learning Control
• User-Orientation / Navigation	• Help Functions
• Software-ergonomics	• Examples
• Content	• Feedback
• Internet functions	

Table 1: Categories of the Group Discussion

Work Independently

69% of the men and 50% of the women want to choose between different installation types. They want to have the possibility to install only parts of the program, for example a laptop version. 67% of the men and 81% of the women want some kind of explanation of how to use the program.

Students want to customize their learning material. They want to use bookmark functionalities and virtual highlighting pens. 52% of the men, and 88% of the women consider it important to post their own comments on a page. 94% of the women, and 88% of the men want to be able to use bookmarks. 93% of the men and 88% of the women want pages they have visited to be marked. A highlighting pen is requested almost equally by 69% of the women, and 62% of the men. 60% of the men and 50% of the women find it necessary to be able to customize their learning material by exporting parts into different programs (for example Power Point).

Students want to be able to use the VLE intuitively. They do not want to spend very much time to get used to the navigation. 88% of the men, and 50% of the women want the layout of the VLE to comply with common standards (for example Windows).

The majority of the students want learning sequences to be between 30-45 minutes. 44% of the women want the VLE to be server-based to enable working in groups. Only 24% of the men find this important. On the contrary, when asking if they want group work, 43% of the men said they did not want to VLE to support group work. Only 12% of the women wanted the VLE not to support group work. 67% of the men want the VLE to be accessible over the internet, 50% of the women thought so, too.

Self Assessment

Students prefer "pull-information" rather than "push information". They want to decide what they want to learn and when they learn it. 67% of the men, and 63% of the women want to be able to choose if explanations to questions are based either on text or on mathematical formulas. 83% of the men and 100% of the women want to choose exercises varying in difficulty levels i.e. beginner, advance and expert. 62% of the women and only 31% of the men want praise from the VLE if they answer a question correctly.

On the one hand students would like to use the VLE on their own, without being dependent on a teacher, but on the other hand, they want the VLE to try to simulate a classroom atmosphere. If the student does not understand an explanation in class he can ask the teacher to explain it in different words, and that's what 88% of the women and 76% of the male students are now asking from the VLE. They would like the VLE to have more than one formulation as an explanation to a problem. Getting personnel feedback is important to the majority of the students. 69% of the men and the women want to be able to send exercises to a personnel tutor who corrects these and then gives them feedback.

4 Conclusions

The wish to work independently expresses itself not only in the evaluated figures, but also in the strong participation in the group discussions and the questionnaire. Our students want us to enable them to work independently. "Today's students, young or old, are leaning towards participatory education and are no longer satisfied to be passive recipients of knowledge" (Erskine 1998, p. 7). We realize this, for example by giving them an approximate timing of lessons to help structure their learning activities according to their needs (see Hill 1997, p.76). We support customization of learning material by integrating common features, e.g. bookmarks, comments, highlighting pen etc. and extending them with a tool still in development called SmartBars. It will enable students to show or hide footmarks, diverse highlighting functions, hints to further going literature, notes from the author, notes from the learner etc. (see Reiners 2002). Intuitive navigation within Vorms will be made possible by offering navigation through hyperbolic trees (see Reiners 2002). The development team of Vorms is convinced that hyperbolic trees are very intuitive to use. What students think about this is going to be evaluated in the future. The implementation depends on the results of this evaluation.

We support the student's wish to work flexibly by giving the synchronization between lecture and VLE a high priority. This way we "…can empower students so learn in new ways and to develop higher-order cognitive skills" (Falk 1995, p. 9).

Our students want to influence the difficulty level of exercises and questions and the way problems and exercises are explained. On the one hand, our students want to learn actively in a constructivist way (see Entwistle 1991, p. 340). On the other hand however, they seem to want programmed instruction (see Criswell 1989, p. 4) because they want the program to make decisions for them, for example giving them a question which has the adequate difficulty level, or telling them in which content areas they still have weaknesses. We are going to continue research in this area, to try to identify the factors that create these different preferences.

The ongoing development of Vorms focuses on those functions, that were evaluated to be of importance to the students. We will transfer the student priorities into the priorities of development. As shown in the questionnaire, there are several differences in the preferences between men and women. The development of Vorms is also going to keeping track of these gender differences.

"In looking at this new learning environment, it is important to remember that the technology does not *cause* the change. Instead, it is probably better to say that the capabilities of the new technologies allow us to facilitate change" (Miller 1996, p. 42). We feel that it is important to integrate those persons into the development process, who are supposed to profit from the new technology. For this reason, we will keep our students integrated in the formative evaluation of the learning environment Vorms.

Abstract: This session describes the educational advantages of and the practical issues in creating a virtual or E-media fieldtrip. The linkages between this educational tool and its further use in heritage management and tourism planning are also explored.

Field trips and site visits are essential components of many academic programmes. These types of activity are incorporated into courses to enable students to experience a location and to encourage a better understanding of an area by observing its characteristics. They are also mechanisms for introducing fieldwork methods and techniques. This teaching method, used in both secondary and tertiary sectors, is well established. It produces positive educational outcomes and is difficult to substitute any other conventional teaching methods to achieve similar results. The choice of location, however, is often an educational compromise, controlled by many factors such as; travel time, cost, amount of suitable accommodation, and effects upon the social and environmental nature of the location.

The material presented does not attempt to suggest that new technologies can adequately replace the field trip or site visit. It does, though, propose using new and evolving technologies as an adjunct support tool or an alternative when an ideal site is inaccessible. Where access to the field site is limited it is often necessary for students to refer to preparatory materials. Restricted access may be due to, danger at the site, remoteness, cost or the physical abilities of a student. Students with restrictions on their ability to reach the location at the specific time of the visit can also be affected, as are those students who are engaged in following a course of study by distance learning.

The educational mixture of the authors involved in this research brings together a number of relatively new and evolving technologies to create a model, or representation, of an island of archaeological and heritage significance which can be used as a "virtual site" for a "virtual fieldtrip".

The virtual reality (VR) environment created integrates visual material within a three dimensional spatial model of a south pacific island, Motukorea in the Hauraki Gulf. The fieldtrip brings together existing technologies for spatial modelling and VR techniques within a hypermedia data structure designed to allow effective and efficient delivery. The presentation includes examples of the Motukorea prototype comprising of panoramic VR with spatial orientation and virtual "fly throughs" of the landscape. The results of this experiment are shown and discussed to illustrate issues of data collection, modelling and display.

This session discusses aspects of technical and pedagogical issues of virtual field trips as educational support tools; it looks at the island, Motukorea (or Brown's Island) as a fully photographed and modelled experiment in VR techniques. Methods are presented which address a number of digital photography and software issues which arose during the project.

The prototype for this virtual fieldtrip can be viewed at:

www.people.auckland.ac.nz/Craig/Motukorea/
